ABSTRACT

13279

This Report describes the current best estimate of the *Ranger VII* spacecraft flight path and the way in which it was determined. Deep Space Instrumentation Facility tracking of the spacecraft was virtually continuous from injection to lunar impact. Dramatic TV photos of the lunar surface were received at the Goldstone tracking station during the last 17 min before impacting the Moon, in what was later to be named the lunar "Mare Cognitum." This event marked the first time that man has succeeded in obtaining closeup photographs of the front side of the Moon. Postflight analysis of the tracking data resulted in valuable determinations of the masses of the Earth and the Moon, tracking station locations, lunar ephemeris scale factor, and lunar radius to the *Ranger VII* impact point, to within 0.4 km.

I. INTRODUCTION

This Report describes the current best estimate of the *Ranger VII* spacecraft flight path and the way in which it was determined. Deep Space Instrumentation Facility (DSIF) tracking of the spacecraft was virtually continuous from injection to lunar impact. Postflight analysis of the tracking data resulted in valuable determinations of the masses of the Earth and the Moon, tracking station locations, lunar ephemeris scale factor, and radius of the Moon at the *Ranger VII* impact point. The impact location of *Ranger VII* is known to within 1.0 km, using the standard deviation as a measure of uncertainty.

The primary objective of the *Ranger* Block III (*Ranger 6* through *9*) flights is to obtain TV pictures of the lunar surface which will be of benefit to both the scientific program and the U.S. manned lunar flight program. The *Ranger VII* spacecraft, which was launched from Cape Kennedy on July 20, 1964, and 68 hr 36 min later impacted the Moon on target on July 31, accomplished its primary objective. This flight, as did *Ranger VI*, dramatically demonstrated the capabilities of Earth-based radio guidance. The *Ranger VII* postflight analysis provided significant determinations of the physical constants mentioned above, which are in excellent agreement with similar determinations realized from the *Ranger VI* postflight analysis.

During the launch phase the *Atlas* and *Agena* stages performed within tolerance and injected the spacecraft into a grazing, backside impact trajectory with the Moon.

The Sea of Storms was selected as the general area of impact, since it was the most favorable location for the prevailing lunar surface lighting conditions. Seventeen hours after launch a near perfect midcourse maneuver was executed. The resultant impact point was only 13 km from the center of the chosen target area. This difference is well within the bound expected and is a combination of the errors in the orbit at the time the desired maneuver was determined plus the tolerances of the spacecraft guidance hardware.

Section II of this Report describes the DSIF transponder orbit determination. Comparisons are made among determinations based on premaneuver tracking only, postmaneuver tracking only, and combined estimates based on premaneuver and postmaneuver tracking. Solutions for the masses of the Earth and the Moon, lunar ephemeris scale factor, and tracking station locations are compared to determinations based upon the *Mariner II* (Venus) and previous *Ranger* missions. The determination of the lunar radius at the *Ranger VII* impact point is also presented. The final TV pictures serve as an independent check on the lunar impact point as estimated from the orbit determination process.

Section III discusses the operational considerations associated with the midcourse maneuver policy and the execution of the maneuver. The postflight evaluation described in this Section shows that the response of the spacecraft to the maneuver turn and velocity increment commands was well within the expected tolerances.

Section IV summarizes the key spacecraft events for the mission, and it describes the *Ranger VII* orbit in terms of its trajectory parameters near the Earth, in translunar flight, and near the Moon.

Section V describes the Air Force Eastern Test Range (AFETR) tracking of the *Agena* launch vehicle. The Eastern Test Range (ETR) orbit analysis is divided into three parts: (1) the parking orbit; (2) the postinjection but preretrorocket phases, during which the spacecraft was still attached to the *Agena*; and (3) the postretrorocket orbit of the *Agena*.

Section VI summarizes the key events in the DSIF tracking of the *Ranger VII* mission and gives a general description of the DSIF stations and tracking modes. The determination of the lunar radius at the *Ranger VII* impact point is a direct function of the "recorded" time of impact. The recordings of this event time, as measured by the DSIF Goldstone tracking stations, are presented and discussed.

II. ANALYSIS OF DSIF TRANSPONDER TRACKING DATA

A. Introduction

The purpose of this Section is to present the techniques used to determine the best estimate of the *Ranger VII* spacecraft flight path, and other significant results obtained from the DSIF tracking data. Not only was it possible to determine the spacecraft flight path to a high degree of accuracy, but, in addition, certain physical constants and station location parameters were derived. The 0.06 sec time difference between predicted and observed landing time, and the close agreement between the predicted and observed landing point are both excellent measures of the accuracy of the estimated flight path.

The tracking data are divided into two logical blocks: (1) data taken prior to midcourse maneuver execution, and (2) data taken after midcourse maneuver execution. Consistent answers are obtained when these blocks are analyzed either independently or combined. In the latter, the uncertainties are significantly smaller. The Orbit Determination Program (ODP) of the Jet Propulsion Laboratory (JPL) (Ref. 1) is the principal analysis tool. This Program utilizes an iterative, modified-least-squares technique to find the initial conditions at injection epoch which causes the weighted sum of squares of the residuals (observed minus computed) to be minimized. The

term "modified" is used to indicate that the weighting of individual data types is accomplished in a different manner than in the usual least-squares method.

The initial real-time estimate of the *Ranger VII* spacecraft orbital elements, and initial DSIF acquisition information were provided by ETR. These elements were obtained from tracking the *Agena* vehicle C-band transponder during the period from injection into lunar transfer orbit to *Agena*–spacecraft separation by the ETR tracking stations. ETR tracking data were not used for the flight path determination results presented in this Section. A complete discussion of the ETR data may be found in Section V.

B. Summary of Data Used in Orbit Determination

The DSIF tracking stations provided continuous tracking data from shortly after transfer orbit injection until lunar impact. Figure 1 summarizes the tracking station view periods and their data coverage for the entire mission. Figures 2, 3 and 4 are tracking station stereographic projections which show the trace of the spacecraft trajectory for the view periods shown in Fig. 1. A more complete sequence of tracking events and ground station tracking modes may be found in Section VI.

Table 1 summarizes the tracking data used for both the inflight and postflight orbital calculations and analyses. This Table provides a general picture of the performance of the data recording and handling systems. The JPL Tracking Data Editing Program (TDEP) (Ref. 2) is used to edit all incoming tracking data, and to prepare a data tape for input to the ODP. The total number of data points received are shown in column 3, and the number of points rejected by the editing program are shown in columns 5, 6, and 7. The points in column 5 are the result of applying a doppler differencing test to detect gross errors. Hence, whenever a bad point is found, the following point will automatically fail the difference test and be rejected. It should be noted that during flight operations, no attempt is made to reconstruct data points which were rejected for bad format. A data point is given a bad data condition code when automatic detectors, at the tracking stations, sense that the data would be unusable. These detectors have manual overrides which are used whenever an equipment malfunction is suspected, and during periods when the transmitter is being retuned prior to sending commands to the spacecraft or transferring transmitting assignment to another station. The reason for the excessive number of points shown in column 7 for the first pass for Stations 51 and 59 is given in Section VI. Otherwise, the number of rejected points shown in columns 5, 6, and 7 appear reasonable.

The blunder points shown in column 8 result from applying the rejection limits seen in column 9. These limits are based on experience gained in previous missions, and on the philosophy that it is better to immediately reject questionable points, which could create difficulties in converging to an orbit, than to attempt to salvage every point. This is particularly true when very few data are available during the early phase of the mission. The data shown in column 10 were obtained from the data tapes punched at the stations and mailed to JPL at the conclusion of each tracking pass.

[a]Data points are obtained from station data tapes to avoid transmission errors.

[b]Includes 161 points of 10-sec data taken during spacecraft reorientation prior to midcourse motor ignition. These data were not included in postflight orbital computations.

[c]Approximately 564 angle pairs were ignored during real-time computations.

[d]Not scheduled to provide tracking data after pass No. 1.

[e]Includes 43 angle pairs taken while spacecraft was below station horizon.

[f]The last real-time orbit was calculated approximately 1 hr before impact. Hence, 378 good doppler points were not used during flight operations.

C. *Data Weighting and Error Sources*

In the modified-least-squares method used in the ODP, the weighting values for the individual data points are determined by the expected (or measured) "effective variances."[1] The weighting scheme used in the program developed by T. W. Hamilton[2] considers all known error sources to determine the "effective variance." Two classes of error sources are associated with the data used in the *Ranger VII* orbital calculations namely: (1) two-way doppler, and (2) hour angle (HA) and declination (Dec).

The error sources for two-way doppler are:

1. Trajectory computation errors due to rounding errors in the Cowell integration (Ref. 5).
2. Doppler counter rounding errors due to "start" and "stop" gate pulses not occurring at times such that an integral number of cycles has passed, or by variations between "start" and "stop" pulses.
3. Ground station transmitter reference frequency errors either in absolute frequency or reference oscillator frequency drift. The reference frequency is controlled by a temperature stabilized, voltage controlled oscillator (VCO) at Stations 41, 51 and 59, and by either a VCO or a frequency synthesizer (SYNTHESIZER) driven by a rubidium frequency standard at Station 12. The drift rate is 1 part in 10^8/15 min for the VCO, and 3 parts in 10^{11}/hr for the rubidium standard.
4. Doppler counter error due to dropped or added cycles in the presence of a low signal-to-noise ratio.
5. Refraction correction errors due to the difference between the atmospheric model in the ODP and the actual atmosphere at a given time.
6. Spacecraft antenna motion caused by spacecraft tumbling or stabilization motion.

The error sources associated with angular (HA and Dec) are:

1. Angle jitter or variation about the aiming point caused by the antenna drive servomechanisms.
2. Angle correction errors caused by differences between the empirical correction model, which is based on the antenna optical axis, and the RF pointing axis.
3. Angular encoder readout errors caused by inaccuracies in compensation cams. Resolution is plus or minus one count which corresponds to 0.002 deg.
4. Refraction correction errors due to the difference between the atmospheric model used in the ODP and the actual atmosphere at a given time.

The manner in which the error sources enter into the weighting scheme may be seen in the following expression which is used to compute the effective variance σ^2 for weighting a given data point

$$\sigma^2 \overset{\Delta}{=} \sum_{i=1}^{6} s_i^2 \, g_i^2 \, \text{Max}\left\{1, \frac{T_{\text{correlation}}}{T_{\text{sample}}}\right\}$$

where

i = basic error source

$s_i^2 \overset{\Delta}{=}$ variance of the basic error source

$g_i \overset{\Delta}{=}$ sensitivity coefficient

$T_{\text{correlation}} \overset{\Delta}{=}$ "correlation width," in seconds, of the basic error source

$T_{\text{sample}} \overset{\Delta}{=}$ sample spacing, in seconds

Table 2 shows the functional form of the sensitivity coefficients associated with HA, Dec, and two-way doppler. These coefficients are computed in the ODP, and $T_{\text{correlation}}$, T_{sample}, and the variances (s_i^2) are on the data input record supplied by the TDEP. Specifically, T_{sample} is obtained directly from the sample time indicated in the tracking data. $T_{\text{correlation}}$ and s_i^2 are obtained from control cards read into the TDEP in a single-weight code word[3] by the orbit engineer. The numerical values used for $T_{\text{correlation}}$ and s_i^2 are based on a priori knowledge of the individual tracking stations gained from previous

[1]This approach was first used at JPL by A. R. M. Noton in "Effect of Correlated Data in Orbit Determination From Radio Tracking Data," August 1959 (internal communication). Further discussion was given by A. R. M. Noton, E. Cutting, and F. Barnes (Ref. 3). T. A. Magness and J. B. McGuire have developed mathematical expressions to contrast the performance of least-squares, modified-least-squares, and minimum covariance estimators in terms of the eigenvalues and eigenvectors of the data noise covariance matrix (Ref. 4).

[2]T. W. Hamilton, "Apriori Weighting Coefficients," April 12, 1962 (internal communication).

[3]Two-way doppler data for Station 12 requires the use of two-weight codes to reflect the two methods of controlling the transmitter reference frequency; i.e., VCO and SYNTHESIZER.

Table 2. Sensitivity coefficients, g_i, for HA, Dec and two-way doppler

Error source	Sensitivity coefficient		
	Hour angle	Declination	Two-way doppler
1	1/cos (Dec)	1	1
2	1	1	$1/T_c$
3	1	1	ρ/c
4	Δr (HA)	Δr (Dec)	$1/\sqrt{3T_c}$
5	— —	— —	$\Delta r \dot{\rho}$
6	— —	— —	1

$$\Delta r\,(\mathrm{HA}) = \frac{\cos\phi \sin^2(\mathrm{HA})}{\cos^2\gamma \sin\sigma}\,(\Delta r\,\gamma)$$

$$\Delta r\,(\mathrm{Dec}) = \frac{\cos\gamma \sin\phi - \sin\gamma \cos\phi \cos\sigma}{\cos(\mathrm{Dec})}\,(\Delta r\,\gamma)$$

ϕ = geocentric latitude of tracking station

γ = elevation angle

σ = azimuth angle

$\Delta r\gamma$ = refraction correction for elevation angle

$= 57.2957795\ n\ b_1 b_2/340.0$, for $\gamma < 0.3$ rad

$= 57.2957795\ n \times 10^{-6} \cot\gamma$, for $\gamma \geq 0.3$ rad

n = index of refraction, nominally 340.0

$b_1 = 1.0 - (1.216 \times 10^5\, b_3\, \gamma) - (51.0 - 300.0\,\gamma)\sqrt{b_3}$

$b_2 = [7.0 \times 10^{-4}/(0.0589 + \gamma)] - 1.26 \times 10^{-3}$

$b_3 = 1/10^3\,(r - RE)$

r = geocentric radius to spacecraft

RE = Earth's radius

$\Delta r\dot{\rho} = 0.0018958\ [(\sin A + 0.06483)^{-1.4} - (\sin B + 0.06483)^{-1.4}]\ n/340.0$

$A = \gamma + T_c\,\dot{\gamma}/2$

$B = \gamma - T_c\,\dot{\gamma}/2$

T_c = doppler count interval, sec

ρ = range from station to spacecraft

missions and on error models for the various error sources. Table 3 presents values of g_i, s_i^2, $T_{\text{correlation}}$, and the resulting contribution to the total weight from each basic error source computed at two different times along the trajectory. The individual data weights for the entire trajectory for a given orbital calculation may be seen in the tracking data residual listings in Appendix E. It is interesting to note the change in data weight when the transmitter was switched from SYNTHESIZER to VCO at 08:41:32 GMT on July 29th in the premaneuver orbit.

The contribution to the total weight due to spacecraft tumbling was considered to be zero since the only tumbling occurred between injection at 17:20:01 and Sun acquisition at 18:06:52 GMT. During this period 30 sec of usable data were received from Station 59, and 8 min of usable data from Station 41. Figure 4 presents a dramatic example of doppler sensitivity to spacecraft motion. The doppler residuals seen in the Figure were observed at Station 41 during Sun Acquisition sequence. The residuals to the left of 18:00:00 GMT show spacecraft tumbling prior to exit from the Earth's shadow, and those to the right show the motion of the spacecraft while it was searching for the Sun. When the spacecraft was in the cruise mode maintaining Sun–Earth lock, the maximum change in doppler phase due to the limit cycle was 0.1 cycles.

In Table 2 it may be seen that the effect on the total weight for the doppler counter error sources (rounding and added or dropped cycles) may be minimized by using a long counting base. This is accomplished at the DSIF stations by taking continuous count doppler with a dual counter system. That is, one counter continuously counts cycles that have passed from some start time. When it receives a pulse to supply a doppler sample, it transfers its contents to another counter without interrupting its counting action. The contents of the second are then translated from binary-coded decimal (BCD) to decimal and punched on paper tape. Doppler refraction correction (error source 5) is not a predominant error source except possibly for the early part of a mission when the elevation angle rates are high. For this mission, only 30 sec of early usable doppler data were available from Station 59. The transmitter reference frequency drift (error source 3) is a major contributor to the total doppler weight for stations using the VCO; but is negligible for Station 12 when using the SYNTHESIZER. For example, near lunar encounter where the contribution from this source is a maximum, the error attributed to the frequency drift for the SYNTHESIZER is $\sigma^2 = 0.03756 \times 10^{-4}$, and for the VCO it is $\sigma^2 = 375.6 \times 10^{-4}$.

For the angular data types (HA, Dec), the predominant error sources are angle correction errors and encoder errors. During *Ranger VII* correction errors of 0.1 deg and encoder errors of approximately 0.02 deg peak-to-peak were noted. Plots of these errors may be seen in Figs. 5 and 6 in which the residuals represent the error remaining after the angle corrections had been applied. Due to these large errors, angular data were not used in the orbit calculations except during the early phase of the mission. They were very helpful in obtaining the first orbital estimates since there was a scarcity of usable data during the first two hours after injection. The contribution due to refraction correction errors was relatively small and was not used for local elevation angles greater than 17 deg. The affect of angle jitter errors on

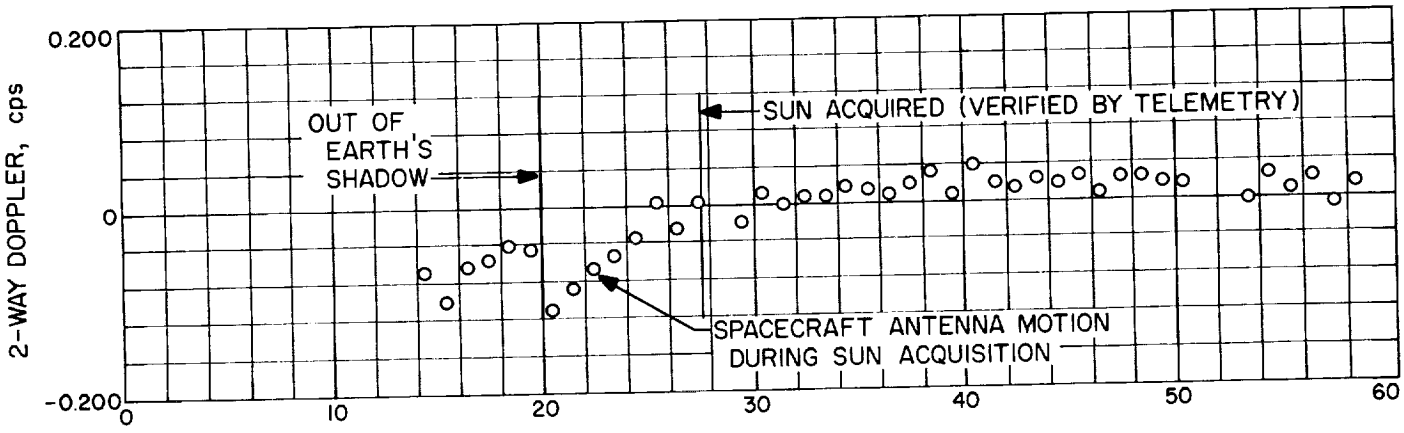

Fig. 5. Station 41 doppler variation during Sun acquisition

the total HA weight was determined by the declination angles seen during the mission. For *Ranger VII*, declination angles ranged between 349 and 7.8 deg. In Table 2 it may seem that this error source contributes very heavily to total HA weight for declination angles near 90 and 270 deg.

For both doppler and angular data, an additional error source exists; namely, the differences in absolute time between the station clocks. For *Ranger VII*, an experimental method was used to determine these differences to within 1 msec during flight operations. This method is based on two stations measuring the time of a specific telemetered event (occurring when both stations have the spacecraft in view) and correcting these times for differences in station–probe range. The event measured was a telemetry synchronization pulse which occurred every 1000 sec. At the stations the event time was measured using an analog recorder operating at a paper speed of 60 in./sec. In addition to the synchronization pulse, a BCD time code and a 100 pps timing reference was recorded. It was assumed that the signal transit time through the equipment (i.e., from antenna to recording device) was the same for all stations. Results of these measurements indicate a 6 msec difference between the clocks at Stations 12 and 41, and a 3 msec difference between Stations 12 and 51. The detailed affect of these biases on the estimate of the *Ranger VII* flight path is small but is being carefully investigated.

The sample spacing to be used at the tracking stations is determined by the tradeoff between doppler counter rounding errors and truncation errors occurring in the doppler frequency computations. The expression used in the ODP for these computations is

$$f(t_{ob}) = \int_{T - \frac{1}{2}\tau}^{T + \frac{1}{2}\tau} \ddot{F}(t)\mathrm{d}t$$

where $f(t_{ob})$ = the integrated doppler frequency, which should be observed by a station at time t_{ob}.

$T = t_{ob} - \frac{1}{2}\tau$

τ = sample spacing

$F(t)$ = the instantaneous frequency of the doppler shift which should have been observed at time t.

This integral is evaluated by expanding a Taylor series about T and integrating term by term leading to

$$f(t_{ob}) = \tau F(T) + \frac{\tau^3}{24}\ddot{F}(t) + O(F^{iv})$$

Thus, the truncation error is a function of τ and the fourth derivative of the frequency (which is, in turn, dependent on the fifth derivative of range). For this mission sample spacing had to be reduced during three phases of the flight: (1) near Earth, (2) during maneuver motor thrusting, and (3) near lunar encounter. For these phases sample spacings of 5, 10, and 10 sec, respectively, were used. At all other times a sample spacing of 60 sec was used.

It is believed that the total weight applied to angular and two-way doppler data is somewhat conservative, and that all error sources which contribute a measurable amount of the total weight have been taken into account.

D. Premaneuver Orbit Based on Premaneuver Tracking Only

Table 4 summarizes the data used for the postflight analysis of the premaneuver data, and presents the statistics pertaining to these data. It will be noted that only two-way doppler data were used in the orbit calculation. Angular data were not used because of biases due to the inadequacy of the angular correction model. These biases may be seen in Figs. 6 and 7, and the correction model errors will be explained more fully in Section VI. From Table 4 it may be seen that the noise level for all stations except Station 59 varied between 0.001 and 0.022 m/sec. At Station 59 the noise level was higher (0.031 m/sec), since a higher sample rate of 1/5 sec was required due to high spacecraft acceleration. Residual plots for the premaneuver data may be seen in Figs. 8 through 13. It should be noted that these plots do not pertain to this particular calculation; but, as will be pointed out in the section on combined results, they deviate by an insignificant amount from the residuals of this orbit.

Table 5, columns 1 through 3, shows the parameters which were estimated and the a priori information used. For this orbital calculation, large a priori uncertainties were placed on all parameters so that the final solution would be determined solely by the tracking data. For the station location uncertainties, the X_1, X_2, X_3 coordinate system (centered at the tracking station) was used. In this system, X_1 and X_2 are in the equatorial plane with X_2 in the longitude direction and X_1 normal to the Earth's spin axis. X_3 is in the direction of the Earth's spin axis. A 1-σ a priority of 500, 500, and 100 m was used for X_1, X_2, and X_3, respectively, and then rotated into the station spherical coordinate system (radius, latitude, and longitude) for input into the ODP.

Column 4 of the Table contains the statistics associated with this orbital calculation at injection epoch, maneuver epoch, and lunar impact. At injection epoch, the smallest uncertainty in the Cartesian orbital elements appears in the X direction, and the largest in the Z direction. This is as expected since the spacecraft orbital plane is almost coincident with the X–Y plane, and the spacecraft motion is predominently in the X direction. The doppler measurement is also in this direction; therefore, X and Y should be well determined. Since Z is normal to the doppler measurement, it will not be as well determined. The uncertainty in the universal gravitational constant times the mass of Earth ($GM_\oplus$) was re-

Table 4. Statistics on premaneuver data

Station	Number of doppler points	No a priority from postmaneuver			With postmaneuver as a priority		With postmaneuver as a priority plus *REM* constraint

[a]Indicates approximate known uncertainty before estimate, which in most cases is a magnitude smaller than a priority actually used.

[b]Space-fixed geocentric equatorial Cartesian coordinates.

[c]Station 59 provided only 30 sec (5 points) of early data and was not scheduled to provide tracking data during subsequent view periods.

[d]These a priori values were used in the orbital calculations for premaneuver data only (column 4), and postmaneuver data only (column 7).

NOTE: All impact statistics are in geocentric coordinate system rather than selenocentric.

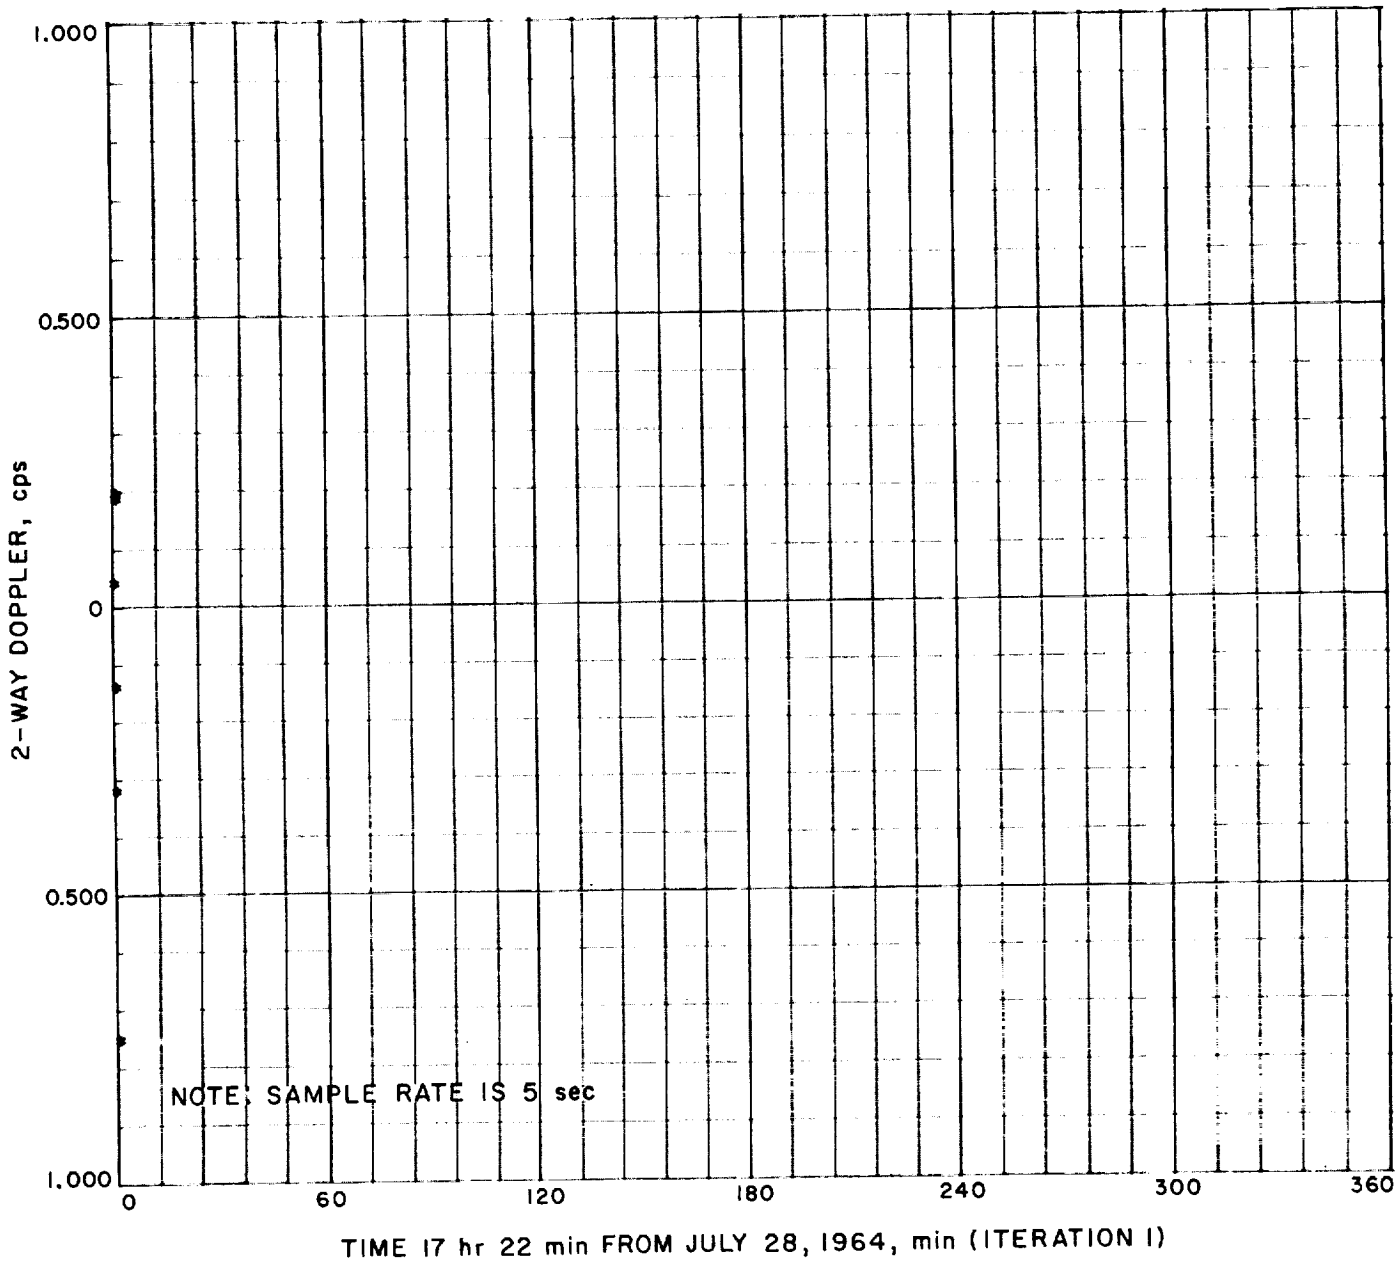

Fig. 13. Station 59 premaneuver pass No. 1 two-way doppler residuals

duced below the input a priority; however, the reduction was not as great as that in *Ranger VI* where it dropped from 10 to 4.25 km^2/sec^2. This is because only 30 sec of usable early data were available for *Ranger VII*; whereas in *Ranger VI*, approximately 2 min of early data were available. Station radius uncertainties were appreciably below the input a priority for all stations except Station 59 where only 5 data points were available.

Numerical values of the estimated parameters are presented in Table 6, column 4. The encounter conditions obtained by mapping the trajectory forward to impact may be seen in Table 7, column 3. For certain parameters, the **B** plane system (defined in Appendix A) is used (Ref. 6). The statistics associated with the encounter parameters are given in Table 8, column 1. In this Table, the semimajor axis *(SMAA)* and the semiminor axis *(SMIA)* define the dispersion ellipse in which impact will occur. *DEL T* is the uncertainty in linearized time of flight along the incoming asymptote. Other terms used in this Table are defined in Appendix G. The correlation matrices at injection and maneuver epochs are presented in Tables 9 and 10.

The conclusions of the premaneuver data analysis are that a good fit was made to all the doppler data, and that the solutions for the physical constants are consistent with presently accepted values.

E. Postmaneuver Orbit Based on Postmaneuver Tracking Only

Table 11 summarizes the data used for the postflight analysis of the postmaneuver data, and presents the statistics pertaining to these data. The noise level in the postmaneuver data varied between 0.001 and 0.003 m/sec, except for the last entry shown for Station 12. The noise level for this block of data was higher, 0.008 m/sec, since a higher sample rate of 1/10 sec was required due to a higher spacecraft acceleration near lunar encounter. Residual plots for the postmaneuver data may be seen in Figs. 14 through 24. It should be noted that these plots do not pertain to this particular calculation; but, as will be pointed out in the section on combined results, they deviate by an insignificant amount from the residuals of this orbit. The difference in noise characteristics between the two methods of controlling the transmitter reference frequency (i.e., VCO or SYNTHESIZER) may clearly be seen in both the residual plots and the standard deviations of Table 11. For example, in Fig. 14 Station 12 was using the VCO for approximately the first 48 min and then switched to the SYNTHESIZER for the remainder of the view period.

Table 11. Data statistics on postmaneuver data

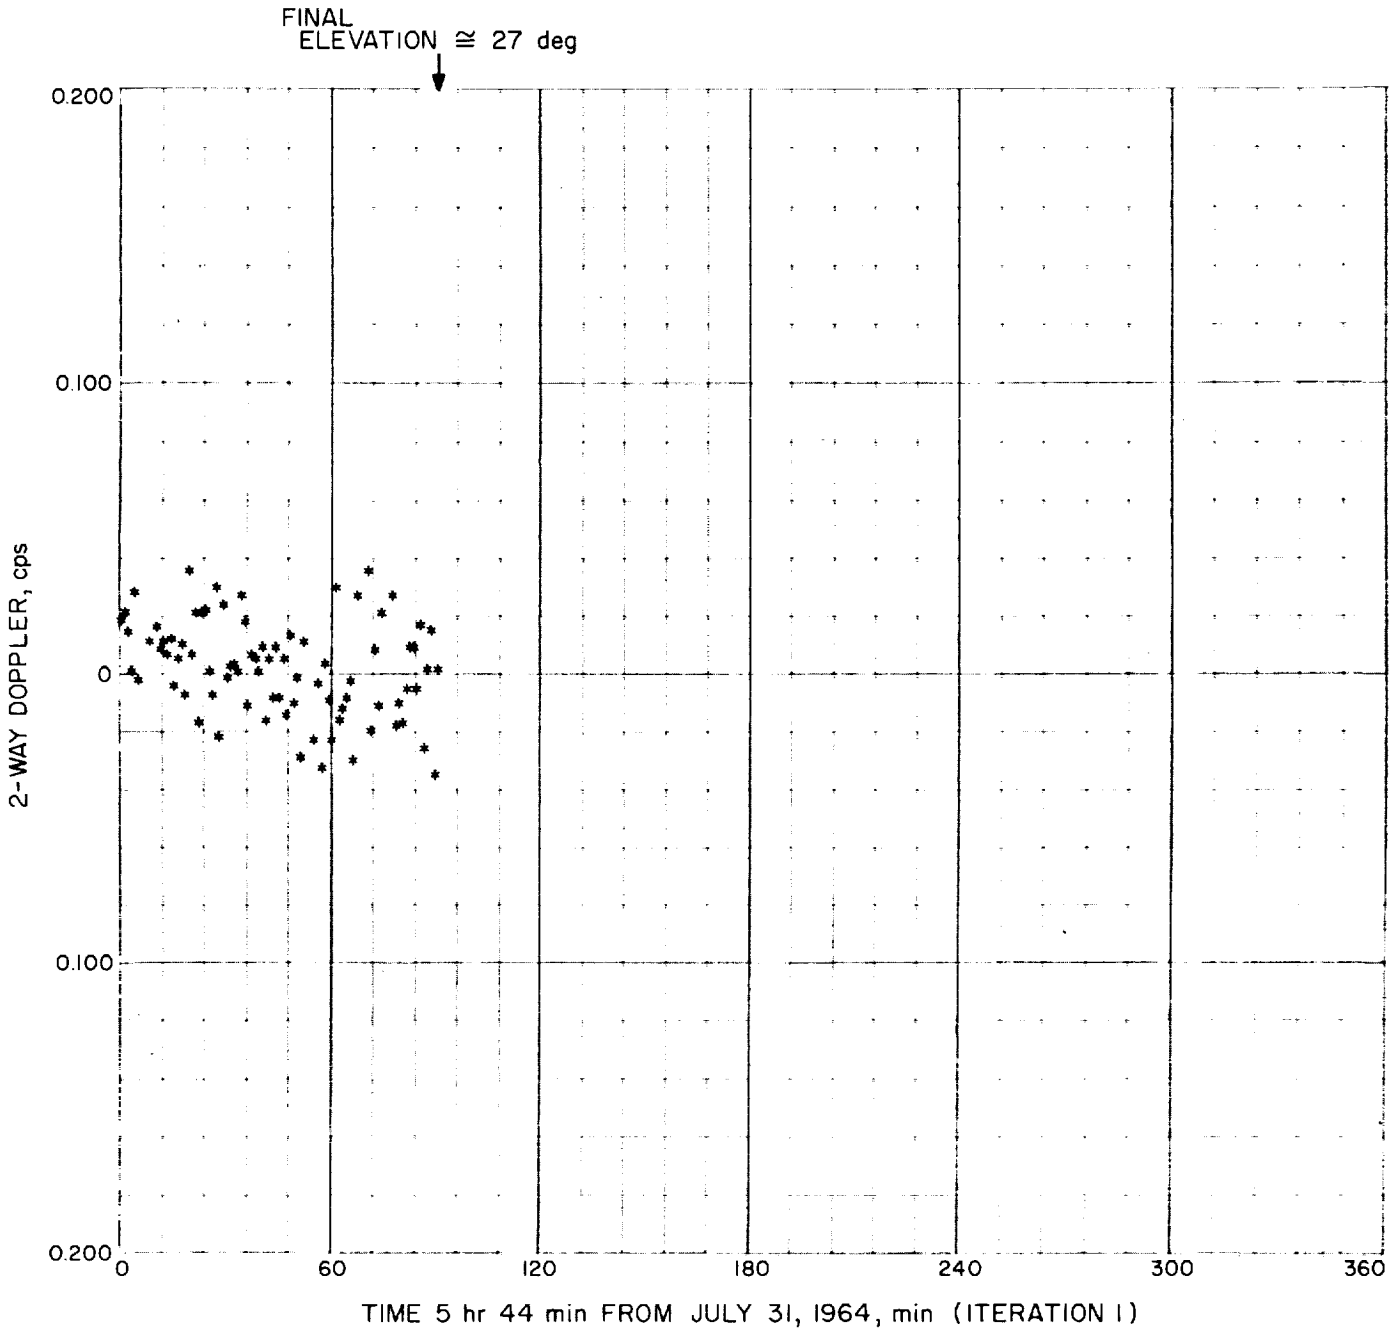

Fig. 24. Station 51 postmaneuver pass No. 2 two-way doppler residuals (start 05:44 GMT)

The noise level for the VCO period was 0.002 m/sec versus a noise level of 0.001 m/sec for the SYNTHESIZER period.

The a priori information for this orbital calculation was the same as that used for the premaneuver study. Statistics associated with the estimated parameters are displayed in Table 5, column 7. The orbital Cartesian uncertainties have been reduced by as much as a factor of 2 from the uncertainties at maneuver epoch based on the premaneuver data only. An even greater reduction may be noted in the statistics at impact epoch. Station location statistics are considered smaller, and the uncertainty in the universal gravitational constant times the mass of the Moon ($GM_{\mathbb{C}}$) has been reduced in magnitude from $\pm$ 4.999 to $\pm$ 0.402 km^3/sec^2. The statistics on the scalar for lunar ephemeris (*REM*) and $GM_{\oplus}$ indicate a rather weak solution for these parameters.

Numerical values for the estimated parameters are given in Table 6, column 7. A consistency check between the premaneuver and postmaneuver orbits was made using the position vector at maneuver epoch. This was accomplished by correcting the premaneuver position vector by an amount determined by the velocity change due to maneuver execution, and comparing this new value with the postmaneuver value. Results of these computations are shown in Table 12. The solutions are well within the 1-σ uncertainties and assure consistency.

Encounter conditions for this orbit are shown in Table 7, column 4. Of significant interest is the fact that the impact time is based on a lunar radius of 1735.6 km. This value was indicated by the results of the *Ranger VI* postflight analysis. During flight operations, using a value based on this, predicted impact was within 0.06 sec of observed impact. It is significant to note that this prediction was made 1 hr before impact. The basis for this lunar radius will be examined in greater detail in a later section. **B** plane statistics associated with the encounter conditions are given in Table 8, column 2. It can be seen that the size of the dispersion ellipse has been considerably reduced from that of the premaneuver orbit. Table 13 shows the correlation matrix of the postmaneuver data at maneuver epoch.

Conclusions based on the analysis of the postmaneuver data are: (1) good fit was made to all data, (2) the solution vector for the physical constants showed a reduction in uncertainties, except for *REM* and $GM_{\oplus}$ in which a weak solution still exists, and (3) the orbital solution is consistent with that obtained from the premaneuver data.

Table 12. Positions at maneuver epoch

Premaneuver only[a]		Postmaneuver only	Postmaneuver–premaneuver
X	156674.70		
ΔX	−0.61		
$X+\Delta Y$	156674.09 ± 3.5	156675.56 ± 2.5	1.5 km
Y	63043.938		
ΔY	−0.371		
$Y+\Delta Y$	63043.567 ± 8.8	63040.365 ± 3.9	−3.3 km
Z	8073.3712		
ΔZ	−0.152		
$Z+\Delta Z$	8073.2192 ± 19.8	8080.9613 ± 8.5	7.7 km

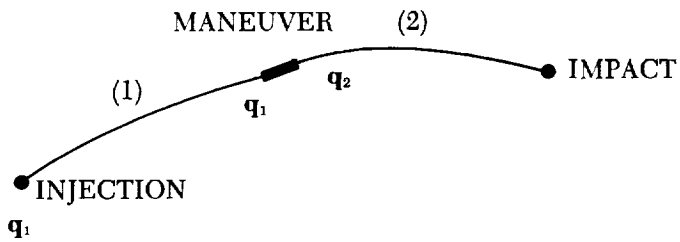
[a] Δ's are the positional changes during maneuver motor burn from the relationship

$$\Delta X = \frac{1}{2} a_x t^2 = \frac{\dot{v}_x t}{2}, \quad \Delta X \rightarrow \Delta Y \rightarrow \Delta Z.$$

F. Combined Estimates Based on Premaneuver and Postmaneuver Tracking

1. Method of Combining Premaneuver and Postmaneuver Data

In order to obtain a better estimate on the postmaneuver orbit, the solution vector and its associated covariance matrix from the premaneuver data were used as a priority for the postmaneuver data. The same was done for the premaneuver orbit where the postmaneuver data were used as an a priori covariance matrix for the premaneuver data. The method used for obtaining the premaneuver estimate using postmaneuver data is[4]



$$\Delta q_1^* = (A_1^T W A_1 + \Lambda_{2_1}^{-1})^{-1} \left[A_1^T W (O_1 - C_1) + \Lambda_{2_1}^{-1} (q_{2_1} - q_1)\right]$$

[4] This method was applied by W. L. Sjogren during the postflight analysis of *Ranger VI* tracking data.

and

$$\mathbf{q}_1^* = \mathbf{q}_{2_1} + \Delta\mathbf{q}_1^* = \text{best maneuver estimate}$$

where

$\Lambda_{2_1} = U(\Lambda_2 + \Lambda_M)U^T$

$\Lambda_2 = (A_2^T W A_2 + \tilde{\Lambda}^{-1})^{-1}$

U = matrix which maps $(\mathbf{q}_2 - \mathbf{q}_m)$ to injection

$\tilde{\Lambda}$ = a priori covariance

$A_2 = \dfrac{\partial \text{ observable in block (2) (postmaneuver)}}{\partial \text{ estimated parameter}}$

$\mathbf{q}_{2_1} = U(\mathbf{q}_2 - \mathbf{q}_m)$

$\mathbf{q}_2$ = solution vector of estimated parameters from block (2) data only

$\Lambda_2 = (A_2^T W A_2)^{-1}$ = covariance on estimated parameters from block (2) data only

W = diagonal weighting matrix on observables

$O - C$ = residuals (i.e., observed data minus calculated data)

Λ_M = covariance on maneuver (diagonal purposely set to a very pessimistic value of 100 m/sec)

$\mathbf{q}_m$ = nominal inflight maneuver estimate

The following expression for the postmaneuver estimate using premaneuver data is very similar

$$\Delta\mathbf{q}_2^* = (A_2^T W A_2 + \Lambda_{1_2}^{-1})^{-1}\left[A_2^T W (O_2 - C_2) + \Lambda_{1_2}^{-1}(\mathbf{q}_{1_2} - \mathbf{q}_2)\right]$$

$$\text{and } \mathbf{q}_2^* = \Delta\mathbf{q}_2^* + \mathbf{q}_m$$

2. Results of Combining Premaneuver and Postmaneuver Data

The estimated parameter statistics based on combining the postmaneuver data with the premaneuver estimate are given in Table 5, column 5. It may be seen that the uncertainties have been significantly reduced from those based on the premaneuver data only. A stronger solution for $GM_\oplus$, $GM_\mathbb{C}$, and *REM* is now indicated. Numerical values for the estimated parameters are shown in Table 6, column 6. The differences between the solution vectors of the premaneuver-data-only orbit and this orbit are well within the uncertainties seen in column 5 of Table 5, except for radius and latitude of Station 12. It may be seen in Table 14 that a high correlation (0.966) exists between the radius *RI*(3) and latitude *LA*(3) of Station 12. A comparison based on computing the term R cos (latitude) for the two solutions shows a difference of 6.3 m. From this it may be concluded that the two solutions for Station 12 location are consistent. Encounter conditions seen in Table 7, column 6, indicate a predicted impact time difference of 7.15 sec between the two premaneuver estimates. This is accounted for by the fact that a different lunar radius was used for the two calculations. That is, without correction, the spacecraft would impact the dark side of the Moon on a grazing trajectory; therefore, the difference in lunar radius is significant. A comparison of the **B** plane statistics (Table 7, columns 1 and 4) reveals a significant reduction in the statistics and the dispersion ellipse for the combined estimate. The correlation matrix for the premaneuver data at maneuver epoch is given in Table 15. The trajectory and the ODP printout, including the data weights and the doppler residuals, for this orbital estimate may be seen in Appendixes B, C, E, and F. Explanations of the printout forms are given in Appendixes D and G.

For the postmaneuver orbit, using premaneuver data as a priority, the estimated parameter statistics (Table 5, column 8) reveal a significant reduction in the uncertainties when compared with the orbit obtained from postmaneuver data only. It may be seen that the uncertainties on the physical constants and the station locations are the same as those obtained by using the postmaneuver data as a priority for the premaneuver estimate. This indicates that the method of combining the two blocks of data was consistent. The differences between the parameter values of the orbit based on postmaneuver data only and this orbit (Table 6, columns 7 and 8) are again well within the uncertainties except for Station 12. The explanation for this is the same as in the preceding paragraph. Encounter conditions (Table 7, column 5) show good agreement with those obtained from the postmaneuver data only, and the **B** plane statistics (Table 8, column 3) are reduced by almost a factor of 2. The correlation matrix from this orbital calculation at maneuver epoch is given in Table 16. The trajectory and the ODP printout, including the data weights and the doppler residuals, for this orbital estimate may be seen in Appendixes C and F, respectively.

The differences between the estimated physical constants and station locations, using the $r \cos \phi$ relationship for Station 12, for the above orbits are well within the respective uncertainties. This, plus the fact that the statistics for these orbits were identical, gives assurance that a better estimate has been obtained for both the premaneuver and postmaneuver orbit. In addition, $GM_\oplus$ and $GM_\mathbb{C}$ are measured at least a factor of 2 better than each separate estimate, and *REM* by a factor of 1.25.

Up to this point, *REM* has been treated as an independent parameter within the ODP. In reality, *REM* is related to $GM_\oplus$ and GM_ζ by the following constraint (Refs. 7 and 8)

$$REM = 86.315745\,(GM_\oplus + GM_\zeta)^{1/3}$$

The *REM* value obtained from the above equation, using the ODP solutions for $GM_\oplus$ and GM_ζ, is 6378.3144 km, and the ODP solution is 6378.3080 km. The difference between these two values is well within the uncertainty; however, the estimated parameter statistics are corrupted by treating *REM* as an independent parameter. To show this, an approach by D. L. Cain[5] was used to apply the constraint to both the best premaneuver and postmaneuver solutions (i.e., the premaneuver orbit with postmaneuver data as a priority, and the postmaneuver orbit with premaneuver data as a priority). Briefly, this method sets the constraint equation equal to G,

$$G = REM - 86.315745\,(GM_\oplus + GM_\zeta)^{1/3} = 0$$

and then uses the method of Lagrange multipliers to minimize the original function and constrain G. That is

$$\mathbf{q}_o = A^T W A$$

and

$$\mathbf{q}_c = A^T W A + \lambda G$$

where

$\mathbf{q}_o$ = original function

$\mathbf{q}_c$ = constrained function

A = residual = observed value − computed value

W = weight on data

λ = vector of Lagrange multipliers

When the first order terms are collected after taking partials to minimize $\mathbf{q}$, the resulting solution can be expressed in terms of the original solution plus one additional term. The new solution vector $\mathbf{q}_n$ is obtained by

$$\mathbf{q}_n = \mathbf{q}_o + \delta\mathbf{q}$$

where

$$\delta\mathbf{q} = \Lambda_o C^T (C\Lambda_o C^T)^{-1} D$$

$$C = \frac{\partial G}{\partial \mathbf{q}}$$

D = the value of G when the estimates for *REM*, $GM_\oplus$, and GM_ζ from the original orbit solution are placed in the constraint equation

Λ_o = covariance matrix from the orbit solution

The constrained statistics are

$$\Lambda_c = \Lambda_o - \Lambda_o C^T (C\Lambda_o C^T)^{-1} C\Lambda$$

The above computations were performed using the solutions from both the premaneuver orbit with postmaneuver data, and the postmaneuver orbit with premaneuver data. These results are presented in columns 6 and 9 of Table 5, in which it can be seen that the uncertainties in the Cartesian coordinates and the physical constants have been significantly reduced. Again note the consistency of the statistics in station locations and physical constants for the two cases.

It remains to be established that the orbit solution is not corrupted by treating *REM* as an independent parameter. This is most easily accomplished by passing the orbit defined by the constrained or new solution vector $\mathbf{q}_n$ through the data. If the constraint does corrupt the orbit, the noise level in the data will increase. Figures 8 through 13 show the premaneuver doppler residuals based on the premaneuver orbit with postmaneuver data as a priority plus the constrained solution vector. Figures 14 through 24 show the residuals from the postmaneuver orbit with premaneuver data a priority plus the constraint. In both cases, deviations from the residuals seen in the previous orbital estimates were insignificant. This can be verified by comparing the residuals in the Figures to those listed in the ODP printouts in Appendixes E and F for the appropriate data block. It is to be noted that these listings pertain to previous orbit estimates and not the constrained solutions. Further verification can be obtained by referring to Tables 4 and 11. For both orbits, the data statistics are almost identical with those of other estimates.

The best estimate of the maneuver can now be obtained by using the constrained solutions. The numerical values are shown in Table 17, and a more complete discussion of the estimated maneuver is given in Section III C.

Conclusions based on the foregoing analysis are that the best estimates for both the premaneuver and postmaneuver orbits are obtained by combining the two data blocks for a given calculation. Further, the most realistic statistics for the estimated parameters are obtained by applying the *REM* constraint to the combined estimates.

3. Observations and Conclusions

a. Station locations. There is considerable information available in the tracking data for determining station

Premaneuver position and velocity[a]	Postmaneuver position and velocity[b]	Position and velocity change due to maneuver (postmaneuver–premaneuver)
$X = 156674.69$		
$\Delta X = -0.63$		
$X+\Delta X = 156674.06 \pm 0.4$	156674.59 ± 0.4	0.5 km
$Y = 63042.780$		
$\Delta Y = -0.381$		
$Y+\Delta Y = 63042.399 \pm 1.8$	63041.361 ± 1.6	−1.0 km
$Z = 8079.7165$		
$\Delta Z = -0.1552$		
$Z+\Delta Z = 8079.5613 \pm 3.3$	8078.2511 ± 4.3	−1.3 km
$DX = 1.4594170 \pm 0.0028$	1.4342624 ± 0.0028	−25.0546 m/sec
$DY = 0.98778791 \pm 0.0046$	0.97256707 ± 0.0046	−15.2208 m/sec
$DZ = 0.28737684 \pm 0.0165$	0.28116743 ± 0.0111	−6.2094 m/sec

[a] Based on premaneuver orbit calculation using postmaneuver data as a priority and *REM* constraint applied.

[b] Based on postmaneuver orbit calculation using premaneuver data as a priority and *REM* constraint applied.

Note: Δ's are the positional change during maneuver motor burn from the relationship

$$\Delta X = \frac{1}{2} a_x t^2 = \frac{\dot{v}_x t}{2}, \quad \Delta X \rightarrow \Delta Y \rightarrow \Delta Z.$$

locations. This is not immediately obvious since examination of the correlation matrixes from the various orbit calculations indicate that there is only information on station longitude. However, if the X_1, X_2, X_3 coordinate system[6] in Fig. 25 is used, it will show that another direction is determined better than longitude.

[6] D. L. Cain, "Tracking Station Coordinate System," June 24, 1964 (internal communication).

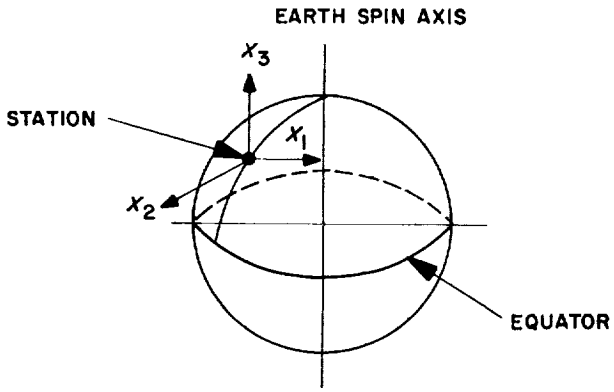

Fig. 25. X_1, X_2, X_3 coordinate system

where X_1 is in Earth's equator, station meridian, normal to Earth's spin axis (such as station longitude)

X_2 is East

X_3 is in direction of Earth's spin axis.

As previously mentioned, X_1 and X_2 may be well determined; but, since X_3 is parallel with the Earth's spin axis, it is not well determined. This is very evident in Table 18 which shows the 10 × 10 normalized covariance matrix on station locations rotated from the radius, latitude, longitude system into the X_1, X_2, X_3 system. The 1-σ a priority used in the initial estimation was 500, 500, and 100 m for X_1, X_2, and X_3, respectively. From the uncertainties in the final estimate, it can be seen that no new information was available on X_3. The best estimate of X_1 and X_2 was obtained from the Station 12 tracking data. This is due to the fact that this Station provided longer tracking coverage (essentially from horizon to horizon) and had the best data quality. Results of *Ranger VII* indicate an improvement in the station location solutions. Table 19 contains a summary of the solutions obtained from the tracking data taken during previous missions. All comparisons are made with respect to land survey locations designated as "old survey." The "new survey"

[b] All differences and uncertainties, σ's, are in meters.

refers to a reevaluation[7] of locations required when the basic reference, the Clarke spheroid of 1866, was changed to the "Kaula" or "165" spheroid. In addition, new survey data for Station 41 (Woomera, Australia) was included. Stations 41 and 51 will soon use rubidium frequency standards which should bring their data quality up to that of Station 12. It will then be possible to use pseudo two-way doppler[8] to obtain horizon to horizon data for each station. Hence, in future missions it should be possible to reduce the location uncertainties for these stations.

[7] J. Heller and H. Kieffer, "DSIF Station Locations," May 1964 (internal communication).

[8] This data type is obtained when one station is transmitting and another station is receiving. Thus one station is receiving two-way and the other pseudo two-way. For the *Ranger* missions the data quality of the pseudo two-way was too poor to use for location studies.

b. Physical constants. Excellent estimates of the physical constants $GM_{\oplus}$, $GM_{\leftmoon}$, and *REM* were obtained from the tracking data. In Table 20 it may be seen that the uncertainty in $GM_{\oplus}$ is only 38% of that estimated by the International Astronomical Union in 1961. Comparison between the *Ranger VI* and *VII* results show very close agreement. Results of *Ranger 3, 4,* and *5* have been included to show the consistency obtained from the *Ranger* missions. Solution uncertainties for *Ranger 4* and *5* are large due to the limited amount of available data (first 8 hr of mission).

Table 20. Physical constants estimate

Source	Value, km^3/sec^2	Standard deviation, km^3/sec^2	Remarks
GM_{Earth} estimates = $GM_{\oplus}$			
Nominal JPL[a]	398603.20	±4.0

Nominal JPL (After *Mariner* '62)	4902.7779	±0.3	Venus cruise data taken during *Mariner* '62
Ranger VI[b]	4902.6182	±0.14	65 hr of tracking
Ranger VII[b]	4902.5801	±0.17	68 hr of tracking

[a]Kaula, 1961 (adopted by the Ad Hoc NASA Standard Constants Committee, Ref. 12).
[b]With *REM* constraint applied.

The uncertainty in the $GM_{\leftmoon}$ solution for *Ranger VII* has been reduced to 57% of the nominal JPL value adopted after the *Mariner II* mission. Comparison between *Ranger VI* and *VII* shows even better agreement than that seen for the $GM_{\oplus}$ uncertainties. The consistency between the two *Ranger* solutions and the *Mariner* solution is of significant interest since they were obtained by two different methods. That is, the *Mariner* solution was obtained by the 28-day periodic effect of the Moon in *Mariner's* cruise phase data (Ref. 9), whereas the *Ranger* solution was derived solely from the direct gravitational force of the Moon. Estimates for $GM_{\leftmoon}$ were not made from *Ranger 3, 4,* and *5* data.

Since large a priori values (uncertainties) were used for the physical constants in the initial estimations (Table 5), it may be stated that the solutions were truly determined from the tracking data. With the constrained estimates on $GM_{\oplus}$ and $GM_{\leftmoon}$, an Earth–Moon mass ratio can be determined as follows:

$$\mu^{-1} = \frac{GM_{\oplus}}{GM_{\leftmoon}} = \frac{398601.28}{4902.5801} = 81.3044 \pm 0.0026$$

This value may be compared with the *Mariner* and *Ranger VI* results given below

$$\mu^{-1}_{Mariner} = 81.3015 \pm 0.0034 \text{ (Ref. 9)}$$

$$\mu^{-1}_{Ranger\ VI} = 81.3036 \pm 0.0023 \text{ (Ref. 10)}$$

c. Impact point. The 1.5 sec difference between the ODP-predicted and the station-observed impact time during *Ranger VI* (Ref. 10) caused an extensive reexamination of the JPL Trajectory Program and the ODP, the mathematical models used within these Programs, and the physical system at the observing station. No error sources were found which could account for this time difference. This led to the hypothesis that the actual lunar elevation at the impact point differed from that shown on Air Force Lunar Map LAC 60 (Ref. 11). To account for the time difference, a 3 km decrease in elevation would be required. An elevation of 1735.3 ± 0.2 km resulted from subtracting 3 km from the 1738.3-km elevation shown on LAC 60. For *Ranger VII*, a time difference of 1.14 sec results from using the nominal lunar radius of 1738.09 km (Ref. 12). To account for this, a decrease in elevation of 2.7 km would be required. This amount, when subtracted from the 1737.9 km elevation shown on map LAC 76 (Ref. 13) gives a lunar elevation of 1735.2 ± 0.4 km at the *Ranger VII* impact point. The *Ranger VI* and *VII* results (summarized in Table 21) are consistent. A comparison between the *Ranger VI* lunar radius and Yaplee's measurements (Ref. 14) may be found in Ref. 10.

The best ODP estimate of the lunar latitude and longitude of the *Ranger VII* impact point is −10.70 and −20.67 deg (Table 7, column 5), respectively. The uncertainty on this point is bounded by the selenocentric dispersion ellipse having a *SMAA* of 1.59 km and a *SMIA* of 0.36 km (Table 8, column 5). Preliminary values of latitude and longitude, based on analysis of *Ranger VII* lunar TV photos and Air Force lunar maps, are −10.62 and −20.59 deg (Table 7, column 6), respectively.[9] In

[9]These are preliminary values obtained by personal communication with D. E. Willingham of JPL.

[b] ODP calculated impact time based on a lunar radius of 1738.09 km.

the TV records, the location of the impact point is well known with respect to surrounding topographic features. However, at control points located within a 2-deg circle of the impact point, there is a ⅓-km uncertainty in the location of the grid lines. The difference between the ODP estimate and the TV estimate (ODP − TV) is −0.08 deg for both latitude and longitude. On the lunar surface, these differences are approximately equivalent to 2.4 km. Figures 26 and 28 are advance unedited proofs of new lunar charts based on *Ranger VII* TV records, and Figs. 27 and 29 are unedited sectional details of Figs. 26 and 28, respectively. All Figures show the trace of the TV camera lens reticles converging to the impact point. The numbers appearing near the traces are TV frame numbers. In Figs. 28 and 29 the spacecraft trajectory as determined from the TV photos (represented by the heavy dashed line in the upper left portion) is also shown converging to the impact point.

4. Limitations

This section discusses the limitations of the *Ranger VII* flight path analysis described in this Report, and predicts the outcome to be expected from a more extensive analysis which will be undertaken after the completion of the *Ranger* Block III (*Ranger 6* through *9*) missions. The *Ranger Block III Summary Analysis* will be performed with the aid of the "next generation" ODP now being developed at JPL.

The ODP used for the *Ranger VII* analysis lacks certain desirable capabilities which will be incorporated in the next generation ODP. The principal items are summarized in Table 22. It is significant to note that errors introduced during computations due to interpolation and the buildup of roundoff error are the major contributions to the two-way doppler weighting sigma discussed in Section II C. This means that the full potential of the DSIF tracking data has not been realized in the *Ranger VII* analysis. The two-way doppler weighting sigma (for one sample/min at Station 12 at lunar encounter) can be reduced from 0.013 m/sec to less than 0.005 m/sec if the computing noise is made negligible compared to the other error sources. The buildup of computing error acts as a low frequency noise source. Such an error usually is not detectable in plots of the doppler residuals such as Figs. 8 through 24. These plots tend to illustrate only the high frequency noise sources.

In addition to the computing noise discussed above, other numerical limitations exist in the analysis. Their existence is illustrated by the fact that certain constraints hold only to a limited precision. Examples include the physical constant solutions and the spacecraft position at the midcourse maneuver epoch. The physical constant solutions obtained from using the results of premaneuver data as a priori information when processing postmaneuver data should be identical to the physical constant solutions obtained when using the results of postmaneuver data as a priori information when processing premaneuver data, in that both orbits use the same set of data but in a different order. Table 6 compares the physical constant solutions from these two orbits. Although the standard deviation of each physical constant shown in Table 5 exceeds the discrepancy between the two solutions, it is still clear that numerical difficulties do exist. For example, $\Delta GM_\mathbb{C} = 0.10$ km³/sec² is a variation in the 5th digit where a variation in the 8th digit may be expected due to roundoff, in that although the same computations are performed, they are accomplished in a different sequence for the two solutions. Notice that $\Delta GM_\mathbb{C}$ is overshadowed by the $\sigma_{GM_\mathbb{C}} = 0.15$ km³/sec² for

Table 22. Limitations of *Ranger VII* analysis which will be overcome for *Ranger Block III Summary Analysis*

Limitation of ODP used for *Ranger VII* analysis	Characteristics of "next generation" ODP which will be used for *Ranger Block III Summary Analysis*
1. Trajectory and most other computations are in single precision. Errors are introduced during computations due to interpolation and the buildup of roundoff error, which are the main contributions to the data weighting sigma, e.g., computing noise contributed 0.012 m/sec out of a total station weighting sigma of 0.013 m/sec for 12 two-way doppler near lunar encounter.	1. Double precision will be used throughout. The computing program will be formulated and the trajectory integration step size can be chosen to ensure that computing noise is a minor contributor to the data weighting sigma.
2. A fixed empirical correction is applied for tropospheric effects. Ionospheric effects are ignored but could appear as an "inward" displacement for a daylight tracking pass.	2. Ionospheric corrections will be applied and a more sophisticated model will be incorporated for the troposphere.
3. Certain operations must be carried out external to the ODP. This sometimes makes an exact iterative solution cumbersome and impractical. These external operations include: a. The application of the $GM_{\oplus}$, $GM_{\mathbb{C}}$, *REM* constraint (maintains the "calculated" period consistent with the "observed" period of the Moon).* b. Velocity increments due to the midcourse maneuver (and the spring separation of the spacecraft from the launch vehicle when applicable) are not automatically "solved for" and the ODP does not properly constrain the spacecraft position at these maneuver points.	3. Maneuver velocity increments will be added to the solution vector and the necessary constraints will be incorporated in the ODP. Tracking data from injection to lunar impact can be processed in a single run as opposed to the premaneuver and postmaneuver segments which had to be treated separately for the *Ranger VII* analysis.
4. Size of solution vector is limited to 20 parameters. Twenty parameters were used for the *Ranger VII* analysis which did not include the maneuver velocity increments, nor all of the tracking station location parameters in the solution vector.	4. Size of solution vector will be nominally 50 parameters but will vary depending on nature of run. This will allow the inclusion of added parameters mentioned under (3) above.

* The lunar ephemeris is an input to the ODP, and the "observed" angular position of the Moon with respect to the Earth is fixed, independent of the $GM_{\oplus}$, $GM_{\mathbb{C}}$, *REM* solutions.

this analysis, but it will not be acceptable for the *Summary Analysis* which should yield a $\sigma_{GM_{\mathbb{C}}} = 0.03$ km^3/sec^2 as discussed below.

The discrepancies in spacecraft position at the midcourse maneuver epoch are shown in Table 17, in which, for example, the spacecraft is displaced 1.3 km in the Z direction above what the magnitude of the maneuver would indicate. The current ODP constrains these positions statistically through the application of an a priori covariance matrix but does not include a physical constraint. The $GM_{\oplus}$, $GM_{\mathbb{C}}$, *REM* constraint was applied as a side condition (Section II F 2), after the ODP processed the postmaneuver data, using the results of the premaneuver data as a priori information. That is, the constraint is not applied in the iterative process but only after the orbit has converged without recognizing the constraint.

The next generation ODP will be formulated and the trajectory integration step size can be chosen to ensure that during postflight analysis computing noise will be a minor contributor to the data weighting sigma. In addition, the maneuver velocity increments will be added to the list of "solve for" parameters, and the equations which constrain the spacecraft positions at maneuver epoch and which constrain the $GM_{\oplus}$, $GM_{\mathbb{C}}$, *REM* parameters will be added to the regression model. Also, the atmospheric refraction model will be improved in that the ionosphere effects will be added, and the tropospheric model will be increased in sophistication. In addition, the size of the solution vector will be increased from its present limit of 20 parameters to allow the inclusion of the maneuver velocity increments, the remainder of tracking station location parameters, and, possibly, timing biases which may be important within the first few hours after launch.

It is desirable to develop a model complete enough so that the "fitters world" will contain all the parameters necessary to represent the "real world" data (remove all trends from the residuals) so that realistic statistics are

Table 23. Physical constant statistics: comparison between *Ranger VII* analysis and *Ranger Block III Summary Analysis*

Physical constant	Standard deviation	
	Ranger VII postflight analysis	*Ranger Block III Summary Analysis*
$GM_\oplus$	1.40 km^3/sec^2 = (3.5×10^{-6}) $GM_\oplus$	0.4 km^3/sec^2 = (1×10^{-6}) $GM_\oplus$
$GM_\mathbb{C}$	0.15 km^3/sec^2 = (30×10^{-6}) $GM_\mathbb{C}$	0.03 km^3/sec^2 = (6×10^{-6}) $GM_\mathbb{C}$
REM	7.3 m = (1.1×10^{-6}) *REM*	2 m = (0.3×10^{-6}) *REM*
Station locations[a]		
x_i (outward radial distance normal to Earth's spin axis)	17.7 m	5 m
$x_{\lambda_i} - x_{\lambda_j}$ (difference in longitude between two stations)	8.8 m	5 m

[a] The *Ranger VII* analysis quotes results for Station 12 and ignores the effect of the ionosphere. The majority of the Station 12 doppler were obtained at night when ionospheric effects were at a minimum.

associated with the solution vector parameters. Table 23 is a comparison of the physical constant statistics between the *Ranger VII* postflight analysis and the *Ranger Block III Summary Analysis*. An improvement factor of 3 is realized for $GM_\oplus$ and 5 for $GM_\mathbb{C}$. The slow relative motion of points on the Earth's crust (which will not be included in the ODP model) may limit the knowledge of station locations to 5 m in the radial direction normal to the Earth's spin axis, and 5 m in the difference in longitude between two stations. The major reduction in statistics is the result of the improved model (i.e., double precision, built-in constraints, midcourse maneuver model, improved refraction model) to be used for the *Summary Analysis*; however, some improvement will also be realized from combining the results of the *Mariner* (Venus and Mars) and the other *Ranger* flights for a consistent solution of the physical constants ($GM_\oplus$, $GM_\mathbb{C}$, *REM*, and tracking station locations). Also, data such as TV pictures of the spacecraft lunar impact point will be available as a check on the orbit determination process.

III. MIDCOURSE AND TERMINAL MANEUVER ANALYSIS

A. Introduction

The function of the Maneuver Analysis Group (MAG) of the Flight Path Analysis and Command Team was fully described in the maneuver part of the Report on the flight path of *Ranger VI* (Ref. 10). Summarized briefly here are the guidelines under which the exploration of maneuver alternatives is carried out for both standard and nonstandard flight sequences. The constraints and restraints imposed are as follows:

1. Mission

a. The impact location must have suitable lighting conditions at arrival. A precise quantitative criteria for measuring these conditions is given in Ref. 15 which predicts best results for regions with a lighting angle of 50–80 deg.

b. It is desirable to land in a mare area not far from the lunar equator (approximately within ±10 deg) for compatibility with the *Apollo* program.

c. If no suitable impact location can be achieved, it is desirable to maximize camera coverage of previously unphotographed portions of the Moon with a west-side flyby.

2. Spacecraft and Geometry

a. The magnitude of the corrective maneuver cannot exceed the maximum available.

b. The Earth–probe–near limb of the Moon angle must not fall below 15 deg in order to maintain Earth lock.

c. It is desirable that the flight time be adjusted so that the automatic preset timer on board the spacecraft will activate the fully scanned cameras no later than 5 min and no earlier than 45 min prior to impact.

d. The angle that the roll axis of the spacecraft makes with the probe–Earth line should not be less than 40 deg during the entire midcourse maneuver sequence. Violation of this constraint may or may not result in loss of telemetry during this critical time. Coordination with the Spacecraft Performance Analysis and Command Group (SPACG) is required in flight to determine the severity of the loss, if any, should the null cone be entered. If (c) and (d) may not be simultaneously attained, the timer takes preference over the telemetry.

e. It is desirable that both the midcourse and terminal phases occur well within a Goldstone viewing period.

f. In the terminal maneuver sequence the second pitch turn may not be less than −47 deg. In addition, it may not be greater than +55 deg if accurate roll stabilization is required.

Figure 30 shows several of these constraints mapped onto the **B** plane. The MAG is further able to evaluate in real time, during the execution of the midcourse maneuver sequence, the consequence of any roll and pitch (with some assumed velocity magnitude increment) should telemetry indicate that the turns being executed are significantly different from those commanded. The evaluation, using linear analysis, estimates target parameters for the maneuver being performed and weighs these against the target parameters for the trajectory with no midcourse perturbation. In carrying out the evaluation, a representative from the JPL Space Sciences Division is consulted before the recommendation is made as to whether or not the maneuver is to be inhibited and the spacecraft returned to its cruise mode by sending real-time command (RTC) 8.

The investigation as to the most desired terminal maneuver can be broken into four main possibilities:

a. The nominal terminal maneuver, which aligns the primary optical axis of the TV subsystem along the velocity vector at the point of impact by performing in sequence a pitch, a yaw, and a second pitch.

b. The optimum terminal maneuver, which seeks to make the optimum trade-off between camera smear due to misalignment between the cameras and the velocity and the viewing geometry.

c. A restricted maneuver, which pitches the spacecraft an amount equalling the algebraic sum of the first and second pitch computed in (a), above, thus increasing reliability.

d. No terminal maneuver at all, which further increases reliability.

The constraints on the midcourse maneuver mentioned above, apply here also in choosing the proper terminal maneuver. Figures 31 and 32 depict the midcourse roll–pitch turn and the terminal pitch–yaw–pitch turn sequences.

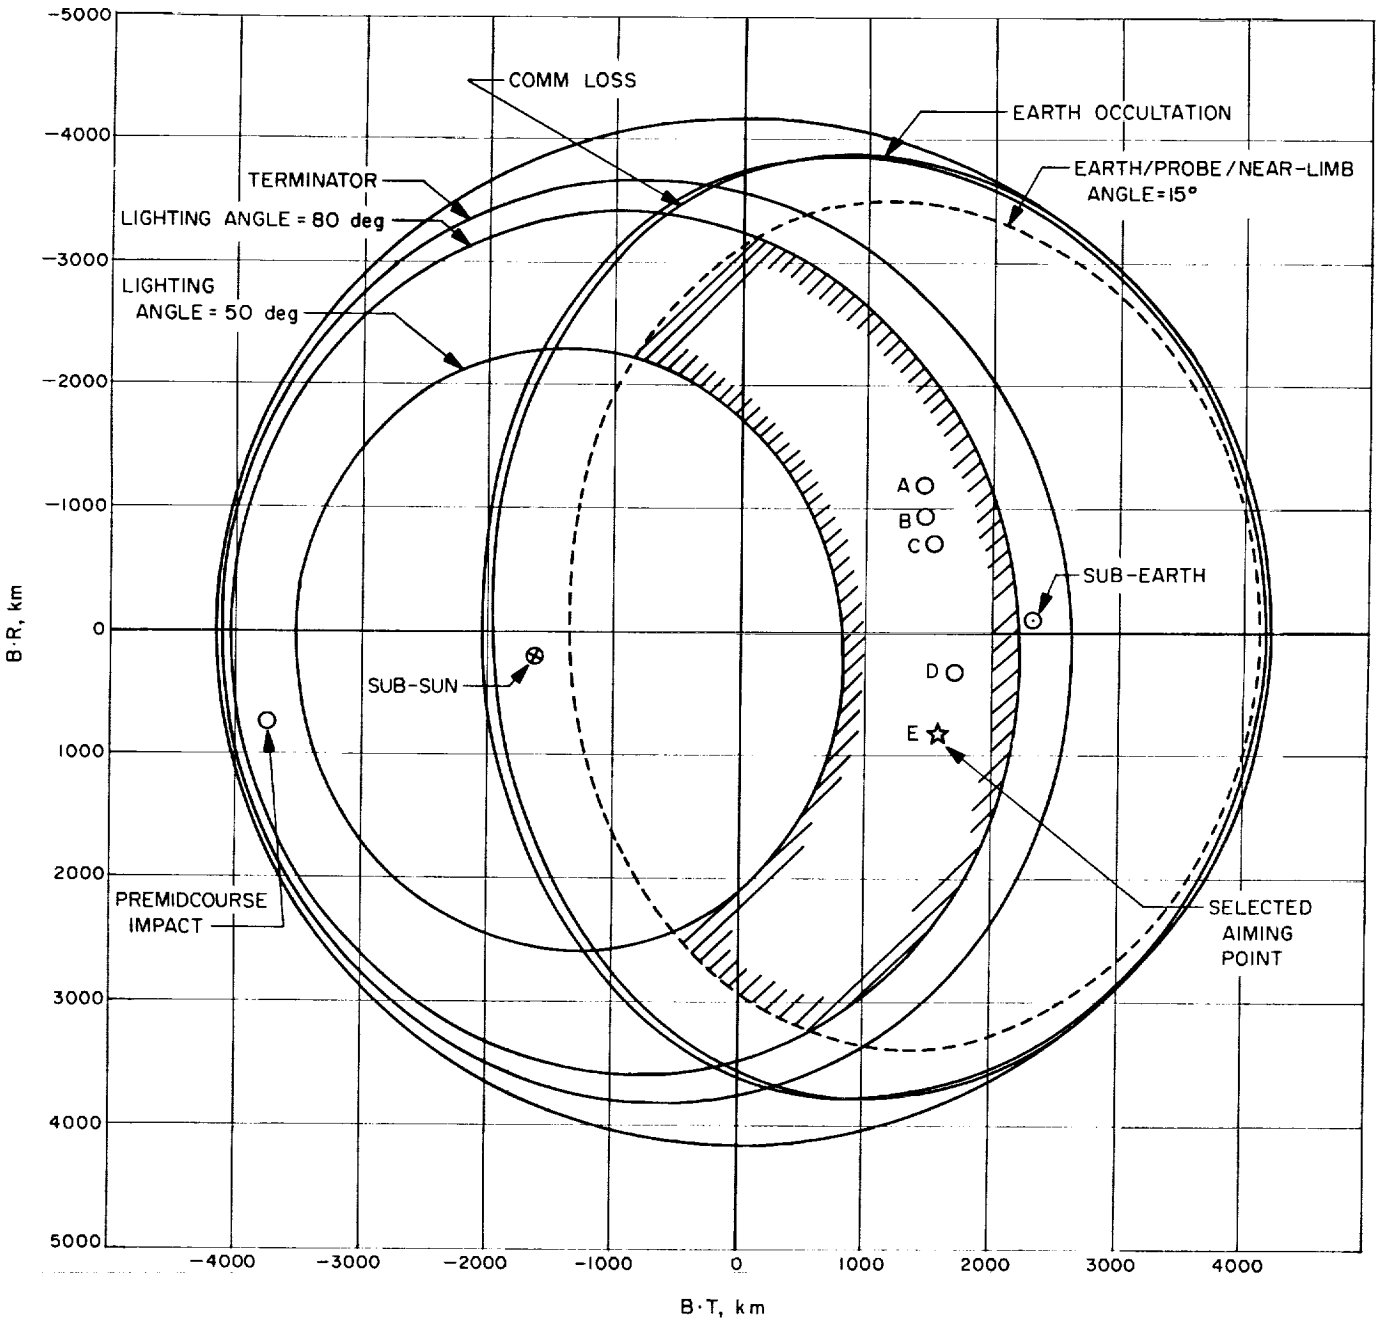

Fig. 30. *Ranger* midcourse maneuver

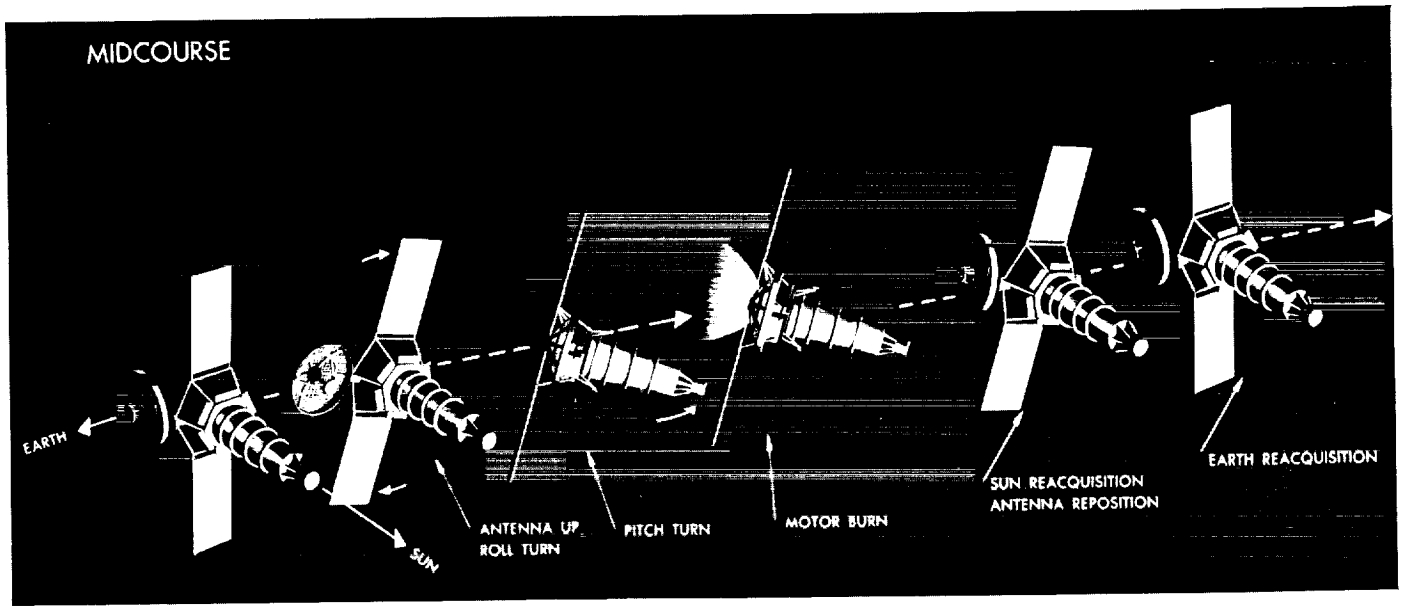

Fig. 31. *Ranger* terminal maneuver

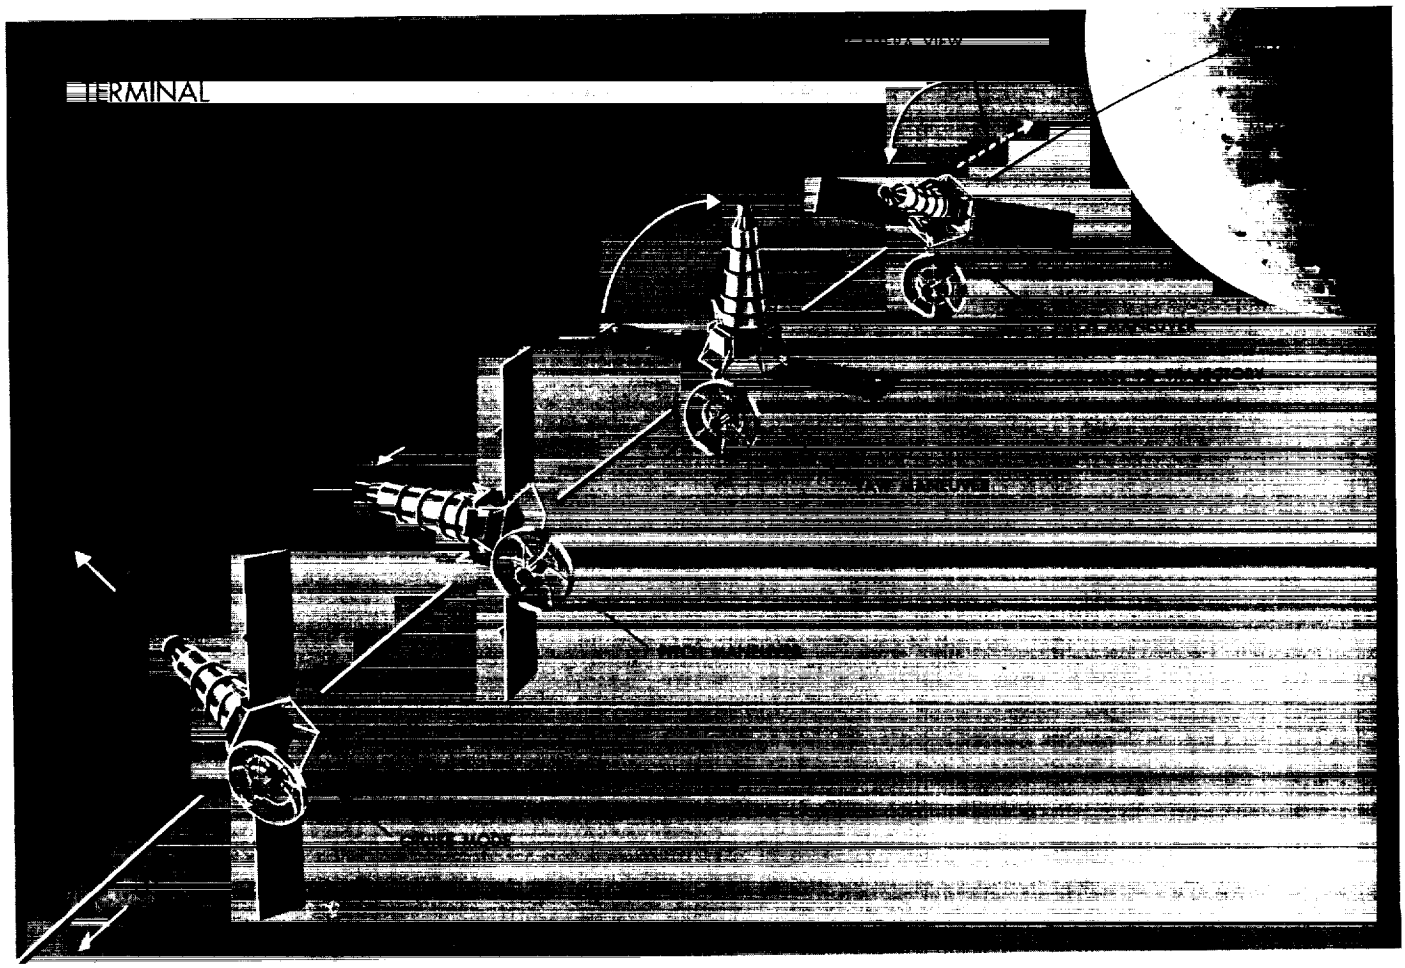

Fig. 32. Capability ellipse of target parameters 16 hr after injection

B. Inflight Maneuver Considerations

Among the various sites considered as a destination for *RangerVII* for the July 28, 1964 launch, the northern part of Mare Nubium at 11 deg South latitude and 21 deg West longitude was selected as most desirable.[10]

With the computation of the first orbit early in the mission, it became clear that the most desired impact point could be achieved with much less than the total 60 m/sec capability of the midcourse rocket motor. The magnitude of the correction needed remained the same, as the orbit estimation was refined prior to the midcourse maneuver. The orbit upon which the final midcourse maneuver computation was based was the nominal pre-midcourse orbit. Table 24 shows the estimate of the arrival parameters of the nominal premidcourse orbit, the target parameters of launch, the desired impact parameters prior to midcourse, and the required change in the terminal conditions. Note that the target point at launch differs by 1700 km from the target point at midcourse, the difference being that the target point at launch is chosen so as to optimize the probability of impacting in the visible lighted portion of the Moon should a spacecraft malfunction preclude a midcourse maneuver, while the target point at midcourse is chosen by the criterion outlined above. The ellipse shown in Fig. 33 centers on the estimate of the target parameters from the nominal premidcourse orbit and describes the total range of the ability to alter these parameters with the 60 m/sec capability of the midcourse rocket.

A summary of statistics of dispersion at the target for the maneuver required is given in Table 25. Listed are the 1-σ values for the *SMAA* and *SMIA* of the dispersion ellipse in the **B** plane along with the uncertainty in time of flight. These quantities are given as contributed by orbit determination uncertainties, maneuver execution uncertainties, and the combined contribution.

[10]Letter dated June 18, 1964 from E. A. Whitaker to D. E. Willingham of JPL describing *Ranger VII* landing sites for the July launch window.

Table 24. Maneuver target conditions

	Aiming point at launch	Premaneuver orbit	Desired arrival point	Correction required
B·RT, km	222	759	820	61
B·TT, km	75	−3799	1607	5406
TF,** hr	68.2	67.23	68.09	0.86

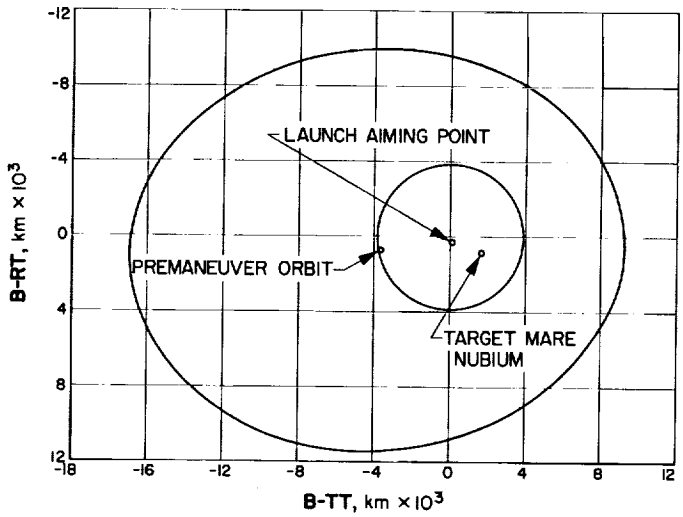

Fig. 33. *Ranger VII* constraints mapped onto the B plane

The flight time of *Ranger VII* was to have been adjusted so that impact would occur 30 min after the backup clock turned on the channel cameras. The maneuver to achieve the impact point and the desired flight time, however, violated the nominal antenna constraint angle of 40 deg. Because of the particular antenna radiation patterns and the particular rotations to be performed by the spacecraft, the number of channels and the time spent by each in the antenna nulls could be reduced by reducing the time from camera activation to impact. Several maneuvers for varying arrival times were computed; each was examined in detail by the SPACG for expected telemetry loss. A flight time with impact occurring 18 min after automatic camera turnon was ultimately decided upon. If, at this time, no terminal orienting maneuver were made, the lunar terminator would be within the field of view of the B camera, thus giving the cameras a wide range of surface illumination. The desired time of flight from injection to impact would be 68.09 hr.

Table 25. Expected target dispersions from orbit determination and midcourse maneuver execution errors

1σ	Orbit determination	Maneuver execution	Combined
Semimajor axis, km	14.6	45.7	47.7
Semiminor axis, km	6.3	35.9	36.8
Flight time uncertainty, sec	5.2	31.4	31.9
Orientation — angle from +**T** axis and **T** to +**R**, deg	6.9	−83.9	−88.3

Having determined the desired target parameters at approximately 3 hr prior to the initiation of the maneuver at 07:27:00 GMT, the final computation was made using the latest determination of the orbit. The resulting required maneuver parameters are entered in Table 26.

Table 26. Commanded maneuver

	Magnitude	Duration, sec	Initiated at GMT
Roll turn	5.56 deg	25	10:00:44
Pitch turn	−86.80 deg	392	10:10:09
Velocity increment	29.89 m/sec	48	10:27:09

Well before the maneuver was to be executed, consideration was given to the possibility of stopping the maneuver sequence with RTC-8, which interrupts the maneuver and returns the spacecraft to its cruise mode attitude, should a malfunction occur during the turning sequence of the midcourse maneuver. This decision of whether or not to halt the maneuver is particularly difficult to make in real time because once the maneuver is stopped, a period of 10,000 sec must elapse before a second attempt is undertaken. This delay due to the recycling period presents the possible problem of having to perform the maneuver over an overseas station with the further thought that the same malfunction that occurred in the first attempt might occur in the second attempt. Furthermore, the delay decreases the capability of the midcourse motor. Taking these considerations into account, the MAG was then prepared to evaluate in real time the direct telemetry readings on the duration and polarity of the turns, assuming the correct motor burn. Fortunately, such preparation was never utilized since the measurements observed in real time during the performance of the maneuver all had the correct polarity and, to within the accuracy of these measurements, were of the exact duration commanded. This, coupled with the real-time doppler reduction discussed elsewhere in this Report, gave almost instant verification that the maneuver had been executed correctly.

After subsequent tracking and determination of the postmaneuver orbit showed that the correction to the trajectory was indeed very close to that desired, consideration was given to performing a terminal orienting maneuver. Prior to computing a terminal maneuver the best estimate of the impact parameters was as follows:

Latitude of impact 10.84 deg South

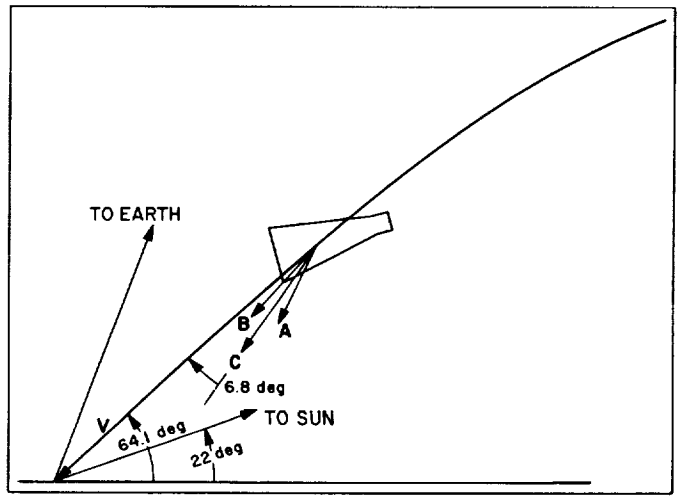
Longitude of impact 20.46 deg West

GMT of impact 31 day 7 mo 64 yr 13 hr 25 min 44 sec

Automatic camera turnon 31 day 7 mo 64 yr 13 hr 9 min 0 sec

Figure 34 depicts the impact geometry with the cameras in the cruise mode orientation. The **C** vector represents the central pointing direction of the four P cameras, **A** and **B** represent the pointing directions for the 25 and 8.4 deg field of view F cameras. The nominal terminal maneuver, if performed, would have aligned the **C** vector with the impact velocity vector. In the cruise mode the **C** vector was 6.8 deg from the velocity vector, and with the path angle shown of 64.1 deg, an impact velocity of 2.62 km/sec, and a shutter speed of 2 msec, the resultant blurring due to camera motion was 0.8 m. That is, the center of the field of view at the time the shutter closed would be observing a point on the surface 0.8 m away from the point viewed at the time the shutter opened. This is an acceptable level of blur; an amount nine times this figure could probably be tolerated and still meet mission objectives.

Examination of the expected picture quality and coverage obtained with various proposed terminal maneuvers revealed that improvement, if any, would be negligible. Adding to this the consideration of greater reliability by not changing the attitude of the spacecraft, the decision not to perform a terminal maneuver was reached.



34. Approach geometry with no terminal maneuver

C. *Comparison of Commanded and Actual Maneuver*

This section examines quantitatively the midcourse maneuver execution errors in terms of effective pitch and yaw pointing errors and midcourse motor shutoff errors, and the uncertainties associated with the estimates of these errors.

Using the estimate of the executed maneuver obtained from Section II F 2, the estimated errors may be summarized as follows:

Estimated error in yaw: −2.04 mrad or −0.117 deg

Estimated error in pitch: 0.83 mrad or 0.047 deg

Estimated error in velocity magnitude: − 0.073 m/sec

Mapping these errors to the target results in a miss of 18.0 km in **B · RT** and 17.1 km in **B · TT** and 19 sec in time of flight. The estimated errors compare with the expected standard deviation for the maneuver performed as follows:

$$1 - \sigma_{\text{yaw}} = 7.6 \text{ mrad}$$

$$1 - \sigma_{\text{pitch}} = 3.7 \text{ mrad}$$

$$1 - \sigma_{\text{vel. mag.}} = 0.8 \text{ m/sec}$$

The uncertainties associated with these estimates are 1.29 mrad, 0.19 mrad, and 0.0037 m/sec, respectively.

Some of the errors involved in executing the maneuver may be accounted for in postflight analysis. These errors consist of limit cycle errors in roll, pitch, and yaw, and resolution errors in the roll and pitch commanded and the magnitude of the velocity added. If these identifiable error sources are removed, then the resulting estimate in the errors is as follows:

Estimated error in yaw with identifiable error sources removed: −2.12 mrad (−0.122 deg)

Table 27. Data used in maneuver error computations

	Roll, deg	Pitch, deg	Yaw, deg
Ideal turn	5.563	−86.803	
Resolution error	−0.103	0.053	
Limit cycle error	0.103	0.126	−0.092

Ideal velocity magnitude = 29.7704 m/sec.
Resolution velocity magnitude error = 0.0914 m/sec.
$\bar{V}_E$ (estimated midcourse velocity vector in m/sec) = (−25.063, −15.223, −6.164]

$$\Lambda_V = \begin{bmatrix} 0.31406381E-10 & -0.92115033E-10 & 0.18141402E-9 \\ & 0.32439815E-9 & -0.60889906E-9 \\ & & 0.11959307E-8 \end{bmatrix}$$

Table 28. *Ranger VII* maneuver execution error estimates

	Yaw			Pitch			Velocity, magnitude		
	mrad	deg	ratio to standard deviation	mrad	deg	ratio to standard deviation	m/sec	ratio to standard deviation	
Estimated error	−2.04	−0.117	0.27	0.83	0.047	0.22	−0.073	0.41	All error sources included
Standard deviation of expected error	7.6	0.436	—	3.7	0.212	—	0.18	—	
Estimated error	−2.12	0.122	0.38	3.96	0.227	1.28	−0.082	0.51	All identifiable error sources removed
Standard deviation of expected errors	5.6	0.321	—	3.1	0.178	—	0.16	—	
Standard deviation of the error in the estimate	1.29	0.074	—	0.19	0.011	—	0.0037	—	Applicable to both sets of results

Estimated error in pitch with identifiable error sources removed: 3.96 mrad (0.227 deg)

Estimated error in velocity magnitude with identifiable error sources removed: 0.16 m/sec

Table 27 shows the data used to arrive at all of the results which are then summarized in Table 28.

The estimate of the velocity added at midcourse $\overline{V}_E$, and the covariance matrix of uncertainties Λ_V associated with it were obtained from the best orbit determination. In this estimate of $\overline{V}_E$ tracking data alone were used (no use being made of the spacecraft's maneuver doppler data). (Further details of this orbit appear elsewhere in this Report.) G. D. Pace was the source[11] used for estimating the value of the standard deviation for the pitch and yaw pointing error and for the velocity magnitude error, while estimates for the resolution and the limit cycle errors were obtained from R. E. Hill.[12]

Again, as in *Ranger VI*, the maneuver happened to be initiated near the zero crossing of the roll limit cycle, thus appreciably reducing the chief contribution to the standard deviation of maneuver execution errors.

IV. *RANGER VII* TRAJECTORY

A. Launch Phase

Ranger VII was launched from ETR at Cape Kennedy, Florida on Tuesday, July 28, 1964 using an *Atlas D/ Agena B* boost vehicle. Launch occurred at 16:50:07.873 GMT with an inertial launch azimuth of 96.6 deg East of North. After liftoff, the booster rolled to an azimuth of 97.1 deg and performed a programmed pitch maneuver until booster cutoff. During sustainer and vernier stages, adjustments in vehicle attitude and engine cutoff times were commanded as required by the ground guidance computer to adjust the altitude and velocity at *Atlas* vernier engine cutoff. After *Atlas–Agena* separation, there was a short coast period prior to the first ignition of the *Agena* engine. At a preset value of selected velocity increase, the *Agena* engine was cut off. At this time the *Agena*–spacecraft combination were coasting in a nearly circular parking orbit in a southeasterly direction at an altitude of 188 km and an inertial speed of 7.80 km/sec. After an orbit coast time of 19.97 min, determined by the ground guidance computer and transmitted to the *Agena* during the *Atlas* vernier stage, a second ignition of *Agena* engine occurred. Eighty-nine seconds later the *Agena* was cutoff, injecting the *Agena*–spacecraft combination in a nominal Earth–Moon transfer orbit. The launch phase ascent trajectory profile is illustrated in Fig. 35, while a sequence of events from launch to acquisition of the Earth by the spacecraft is shown in Fig. 36.

B. Premaneuver Cruise Phase

Injection (second *Agena* cutoff) occurred at 17:20:01 GMT, over the western coast of South Africa at a geocentric latitude and longitude of −12.89 and 15.07 deg, respectively. The *Agena*–spacecraft were at an altitude of 192 km and traveling at an inertial speed of 10.949 km/sec. One minute and 32 sec after injection the *Agena*–spacecraft combination entered the Earth's shadow. The *Agena* separated from the spacecraft 2 min 35 sec after injection, performed a programmed 180 deg yaw maneuver, and ignited its retrorocket. The retrorocket impulse was designed to eliminate interference with the spacecraft operation and reduce the chance of the *Agena* impacting the Moon. Tracking data indicated that the *Agena* would pass the upper trailing edge of the Moon at an altitude of 3660 km about 3 hr after *Ranger VII* impact.

Ranger VII left the Earth's shadow 40 min 5 sec after injection for a total shadow duration of 38 min 33 sec.

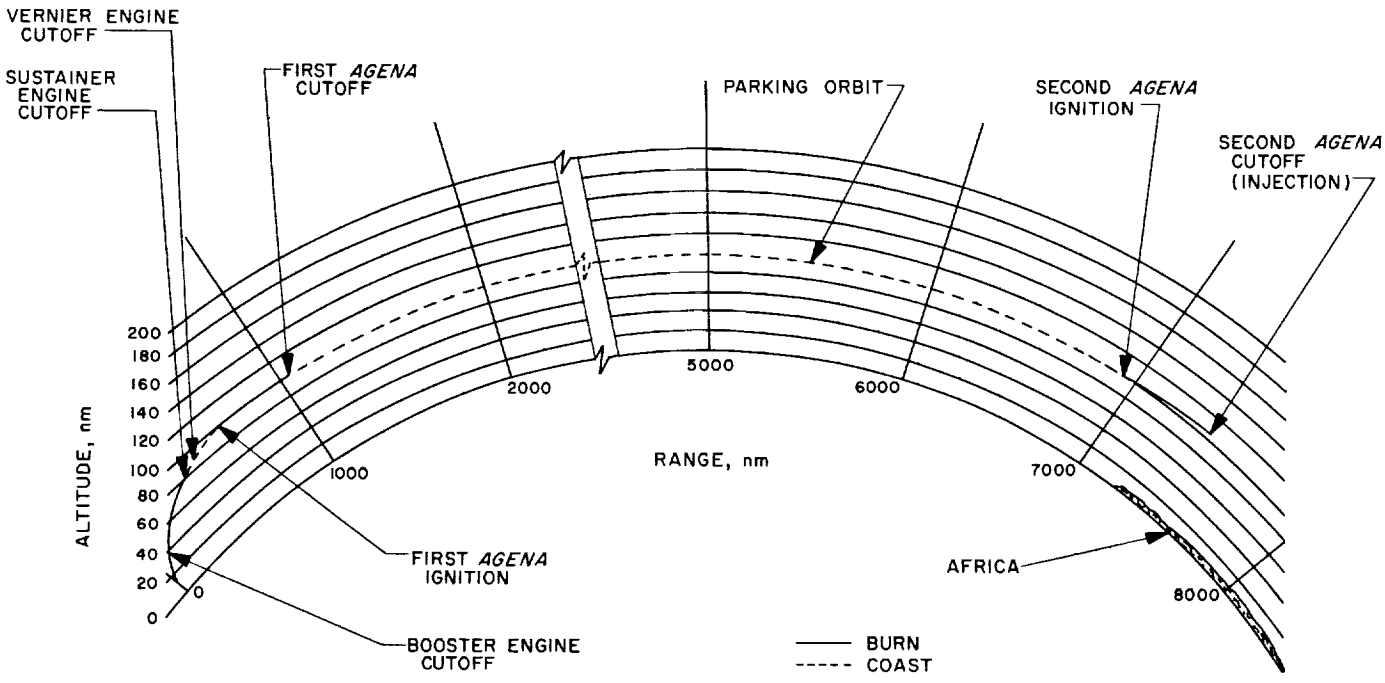

Fig. 35. Ascent trajectory profile

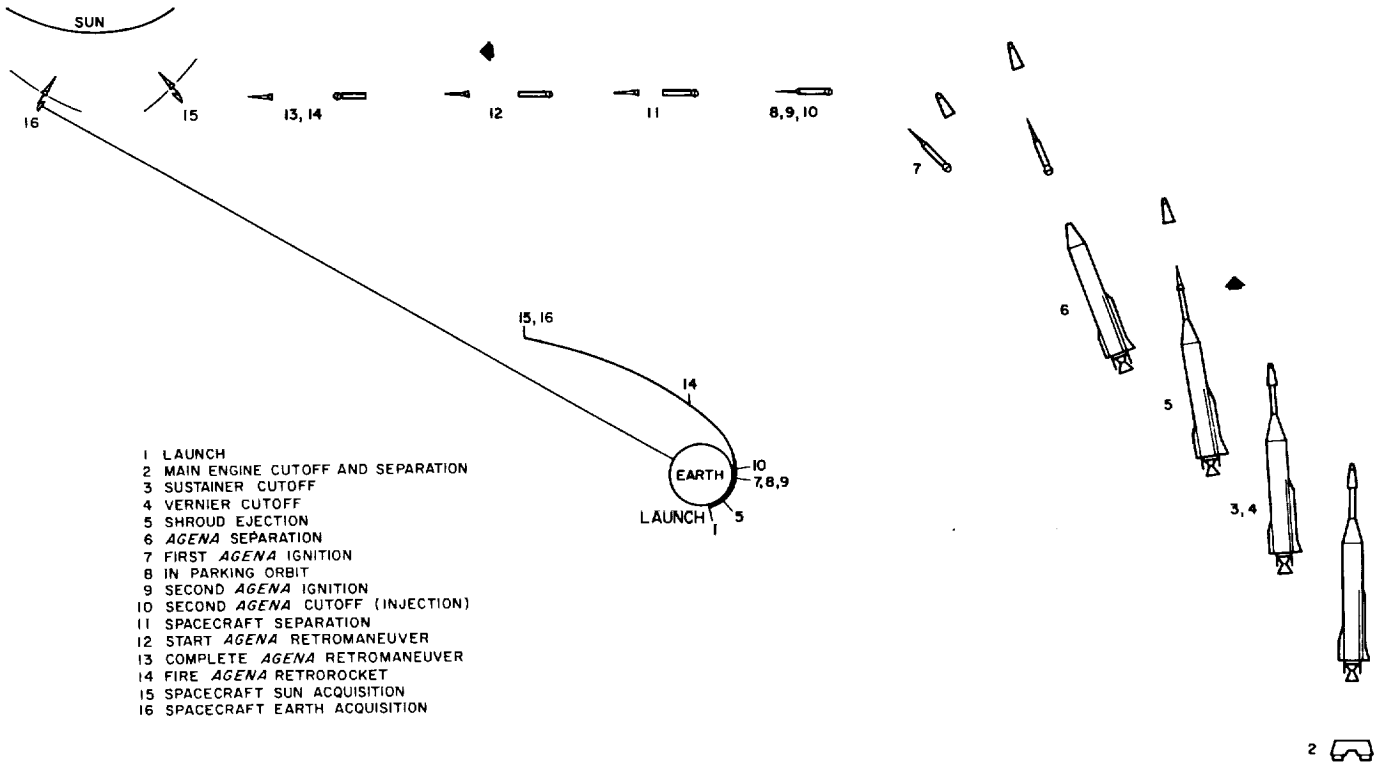

Fig. 36. Sequence of events to Earth acquisition

Sun acquisition had been initiated 9 min 58 sec prior to leaving the Earth's shadow. Five minutes after leaving the Earth's shadow the Sun was acquired. Within an hour after injection, the spacecraft was receding from the Earth in an almost radial direction with decreasing speed. This reduced the geocentric angular rate of the spacecraft (in inertial coordinates) until, at 1.4 hr after injection, the angular rate of the Earth's rotation exceeded that of the spacecraft. This caused the Earth's track of the spacecraft (Fig. 37) to reverse its direction from increasing to decreasing Earth longitude. Plots of geocentric distance and inertial speed for *Ranger VII* as well as Earth–Probe–Sun (EPS), Sun–Probe–Moon (SPM), and Earth–Probe–Moon (EPM) angles as a function of time from launch are presented in Figs. 38 through 40.

Final analysis of premidcourse tracking data showed that without a correction the spacecraft would have impacted the back side of the Moon at a selenocentric latitude and longitude of −12.4 and 201.2 deg, respectively. The transit time from injection to impact would have been 67.396 hr.

C. *Midcourse Maneuver Phase*

In order to alter the trajectory so as to impact a selected aiming point at a selenocentric latitude of −11 deg and longitude of −21 deg, midcourse maneuver calculations indicated a requirement of 29.89 m/sec increment of velocity (60 m/sec maximum capability). In addition, this correction was selected to adjust the flight time from injection to impact to be 68.09 hr, thus allowing the TV camera backup turn on clock to be utilized as designed. To properly align the thrust direction of the midcourse motor for the burn, a +5.56 deg roll turn and −86.80 deg pitch turn were required. The midcourse motor was ignited at 10:27:09 GMT on July 29, 1964 when the spacecraft was at a geocentric distance of 169,000 km and traveling with an inertial speed of 1.786 km/sec relative to Earth. At the end of a 50 sec burn of the midcourse motor, the geocentric distance had increased to 169,075 km, and the inertial speed relative to Earth had decreased to 1.756 km/sec. Analog data received at Goldstone and relayed to the Space Flight Operations Facility (SFOF) at JPL positively indicated that the midcourse maneuver and motor burn had been executed precisely. This was further verified by the observed

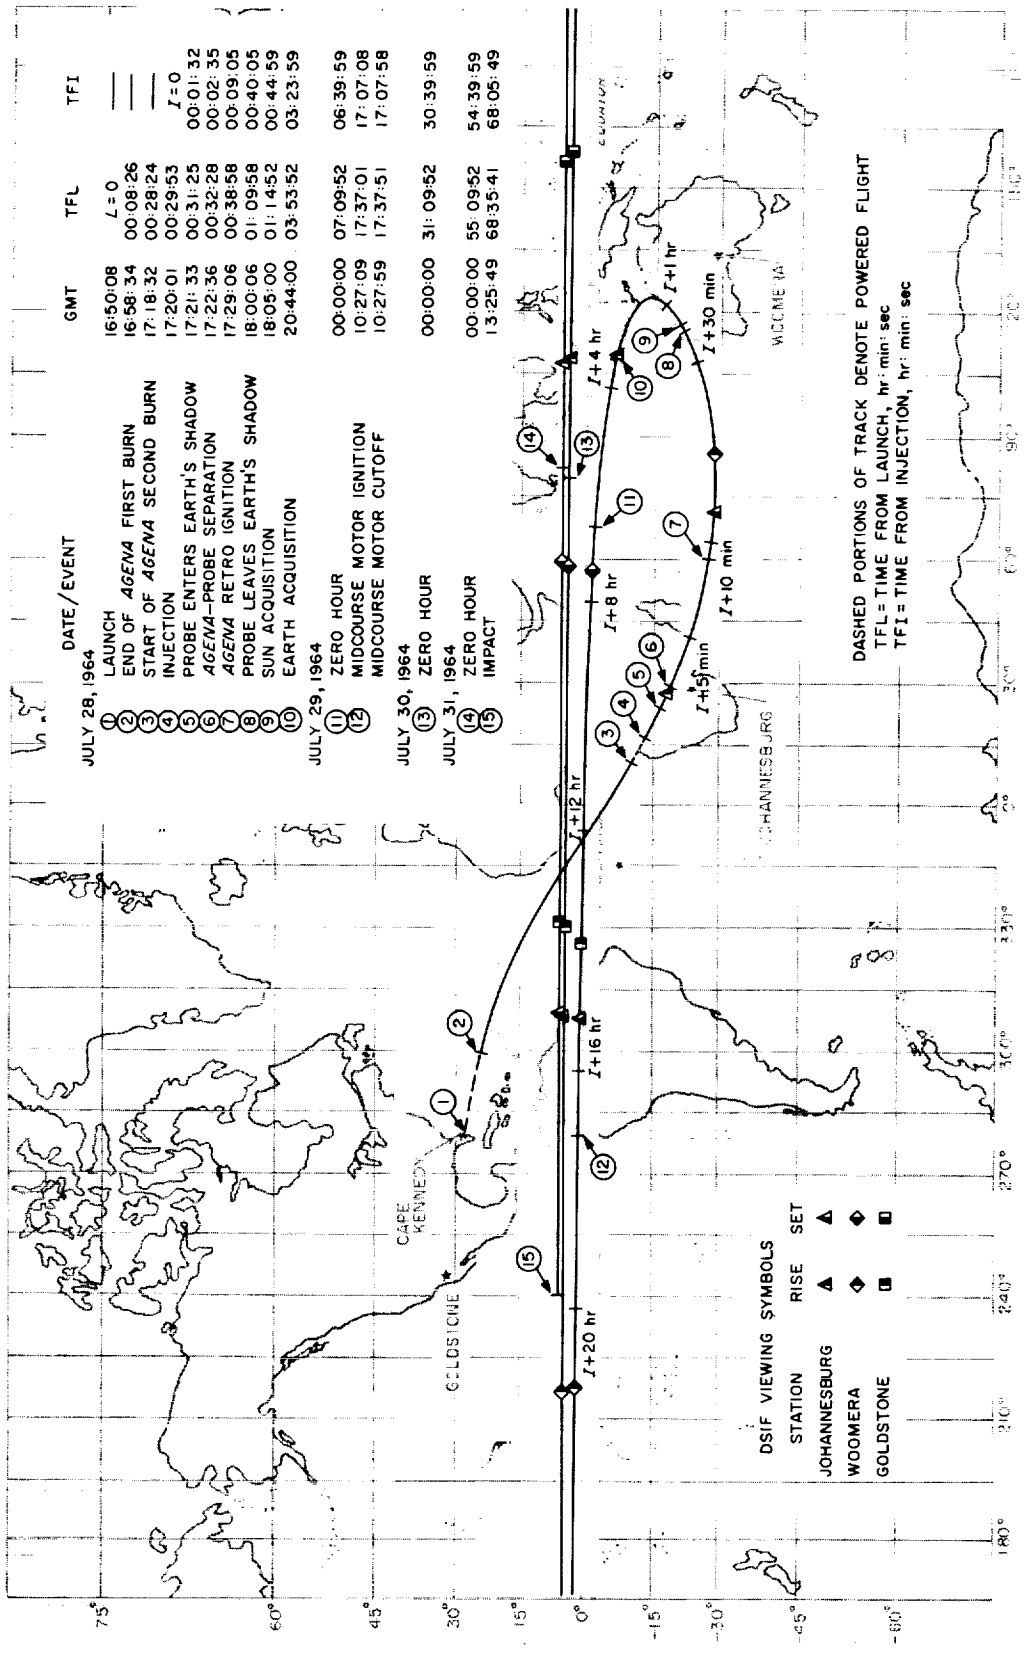

Fig. 37. Date and time chart of significant events

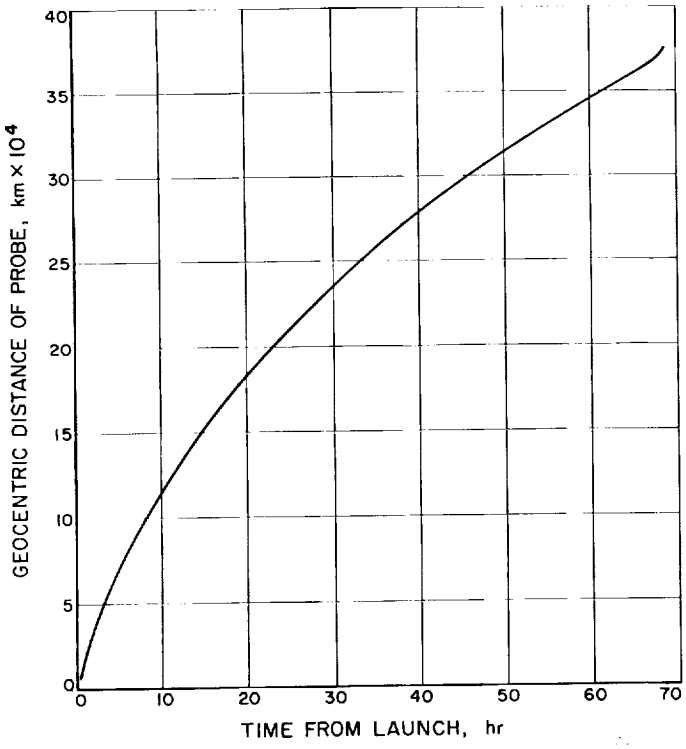

Fig. 38. Probe geocentric radius vs time from launch

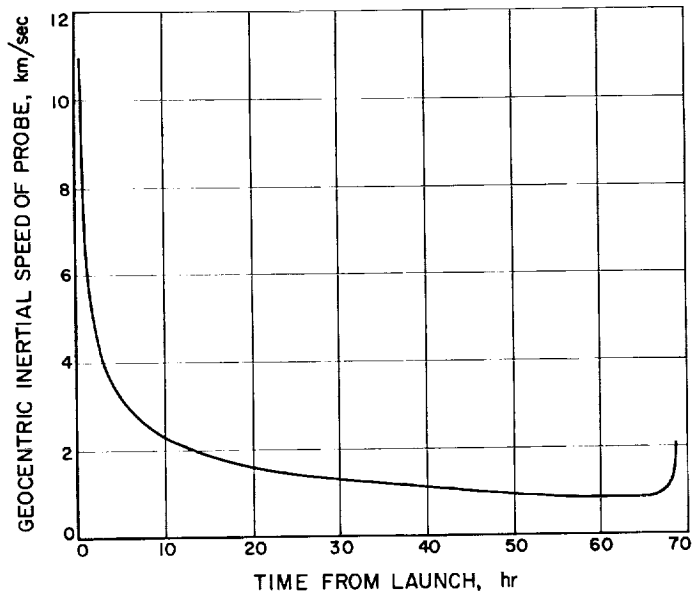

Fig. 39. Probe geocentric velocity vs time from launch

doppler data being essentially the same as those predicted. Injection and encounter conditions for the premidcourse orbit are given in Table 29. Terms used in Table 29 are defined in Table 30.

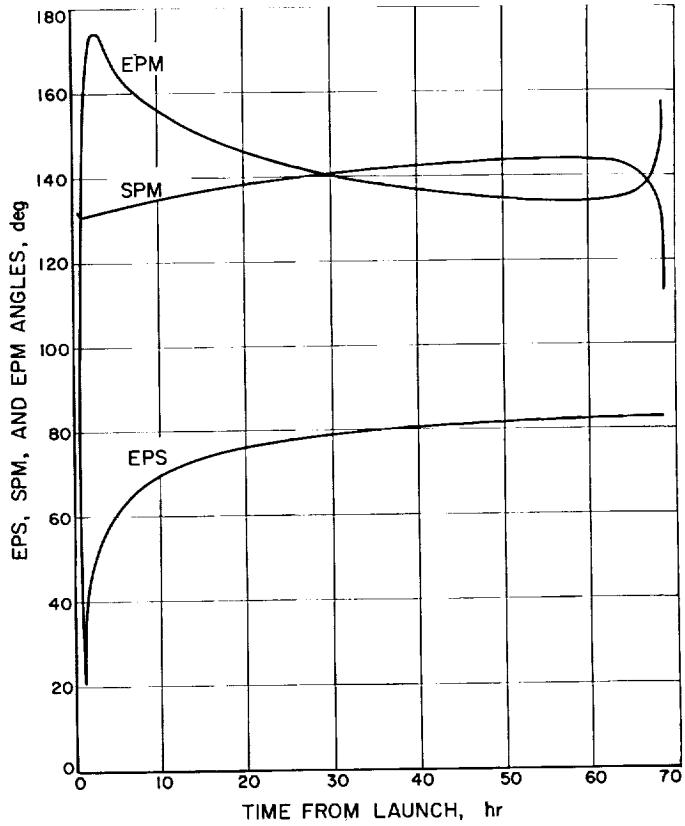

Fig. 40. Earth–probe–Sun (EPS), Sun–probe–Moon (SPM), and Earth–probe–Moon (EPM) angles vs time from launch

D. Postmaneuver Cruise Phase

Following the midcourse maneuver the spacecraft reacquired the Sun and Earth, thus returning to the cruise mode. At about 63 hr after injection and at a geocentric distance of 355,300 km the spacecraft's inertial speed relative to the Earth reached a minimum value of 0.850 km/sec. At this point, the spacecraft was about 28,300 km from the lunar surface with an inertial speed of 1.36 km/sec relative to the Moon. Because of the lunar gravitational field the spacecraft's velocity began to increase.

Postmidcourse tracking data resolved the trajectory's lunar encounter conditions to a high degree of accuracy, with the lunar impact occurring at a selenocentric latitude and longitude of −10.70 and −20.67 deg, respectively, with a flight time of 68.097 hr from injection. The encounter conditions along with the corresponding postmidcourse initial conditions are presented in Table 31. The geocentric spatial trace of the trajectory from injection to impact is illustrated in Fig. 41.

i	Inclination, deg
Ω	Longitude of the ascending node, deg
ω	Argument of pericenter, deg
ν	True anomaly, deg

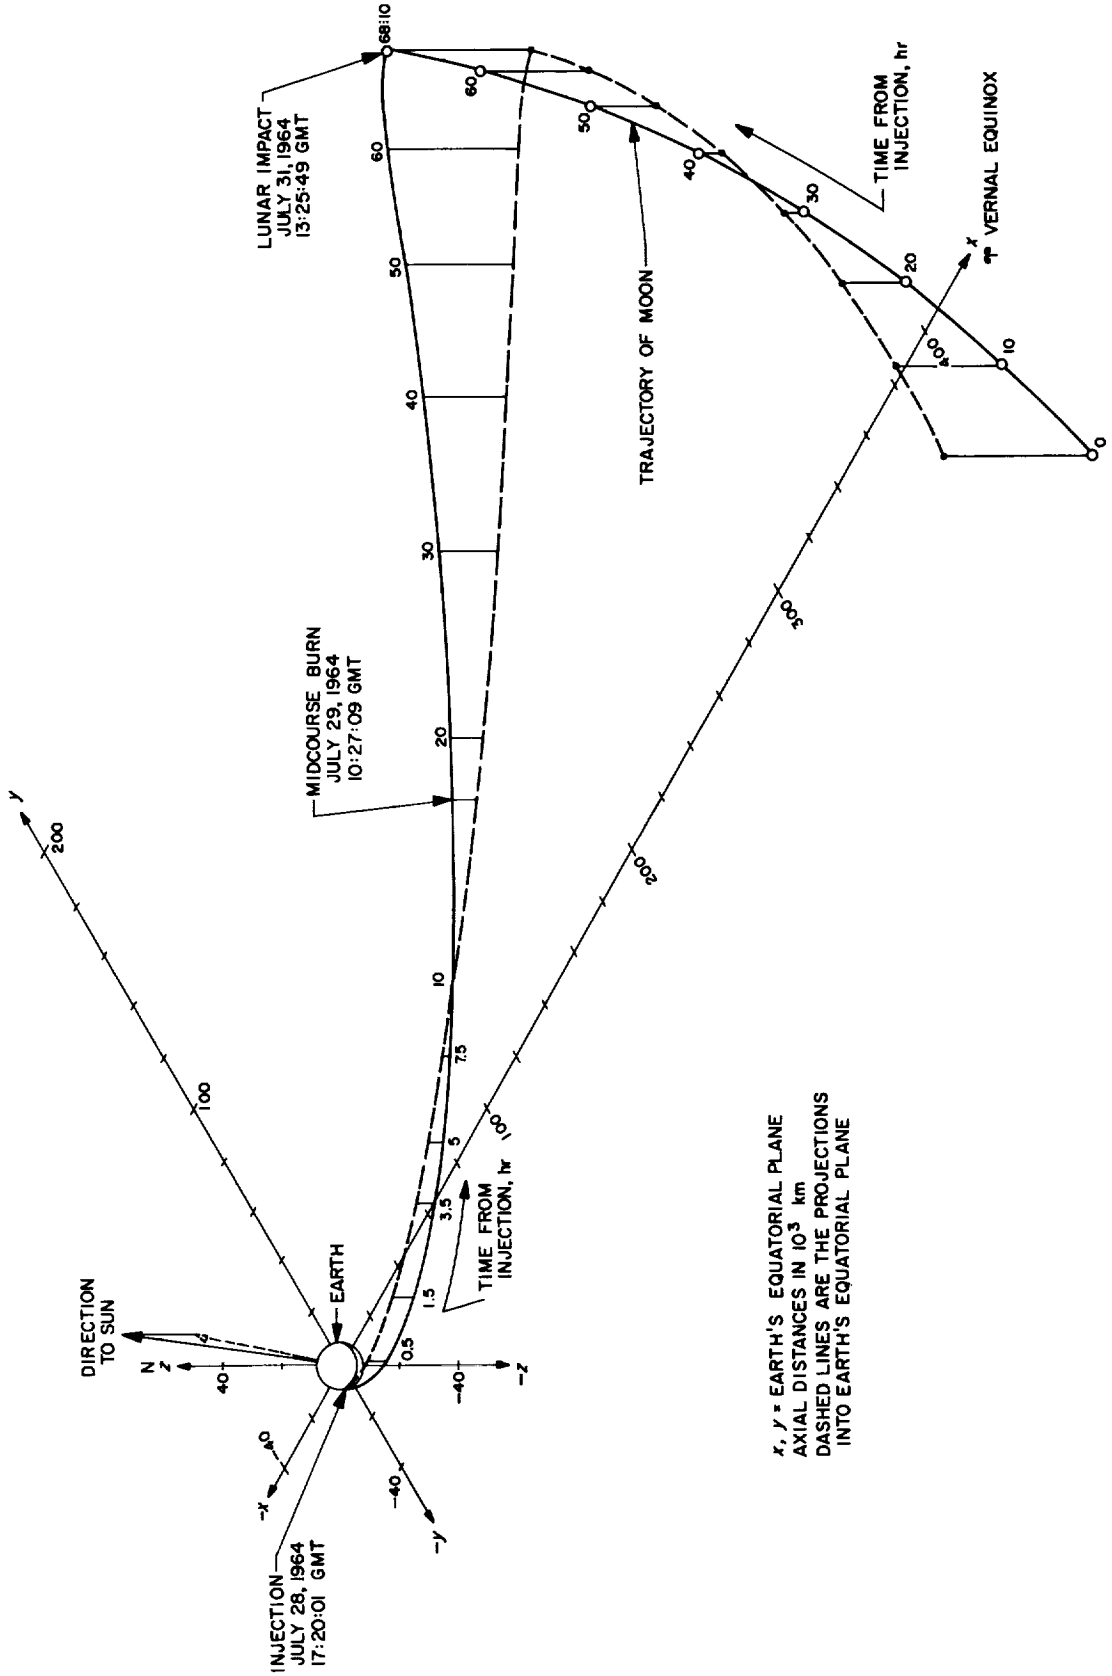

Fig. 41. Geocentric spatial trace *Ranger VII* trajectory

E. Encounter Phase

During the encounter phase the spacecraft raced toward impact with increasing acceleration due to the pull of the lunar gravity field. This effect is shown in Fig. 42 in which the *Ranger VII* trajectory trace to lunar encounter is compared with a hypothetical *Ranger VII* trajectory resulting from a massless Moon. One hour before impact, the speed of the probe relative to the Moon had increased to 1.551 km/sec and was at a lunar altitude of 6390 km. No terminal maneuver was needed at this time to realign the TV cameras' pointing direction.

About 45.5 min before impact, the spacecraft crossed the lunar equator at an altitude of 4933 km. At 13:08:36 GMT at 2126 km above the lunar surface, F channel full power was verified. At 13:12:09 GMT and at 1723 km, P channel full power was also verified. Minutes later at 13:25:50 GMT on July 31, 1964, *Ranger VII* crashed into what was to be named the lunar "Mare Cognitum" at an impact speed of 2.616 km/sec and at a path angle of −64.1 deg. The spacecraft had encountered the Moon in a direct motion along a hyperbolic trajectory with the incoming asymptote direction at an angle of −5.57 deg to the lunar equator, and the orbit plane inclined 26.84 deg to the lunar equator.

The trace of the trajectory on the lunar surface from injection to impact is given in Fig. 43, while the traces of the lunar approach portions of the premidcourse and postmidcourse orbits are illustrated in Fig. 44. The probe's geocentric distance and velocity are given in Figs. 45 and 46, respectively, for the last few hours of flight. The selenocentric altitude and velocity are given in Figs. 47 and 48, and the EPS, SPM and EPM angles for the last hours of flight are in Fig. 49.

A study of the *Ranger VII* trajectory can be made by examining the detailed trajectory printout (Appendixes B and C). Appendix B contains the trajectory listing for the premidcourse orbit from the initial epoch to the midcourse epoch and a lunar impact printout. Appendix C contains the trajectory listing for the postmidcourse orbit from midcourse to lunar encounter. Appendix D, Table D-1, is a key to the trajectory printout. Table D-2 contains the definitions of the trajectory printed quantities. Constants and conversion factors used in *Ranger VII* trajectory computation are listed in Table D-3. The miss parameter **B**, used to measure the miss distance for the lunar trajectory, is defined in Appendix A.

V. ANALYSIS OF AIR FORCE EASTERN TEST RANGE TRACKING DATA

A. Introduction

For the *Ranger* missions, the AFETR is responsible for providing classical orbital elements for both the parking and transfer orbits, and for providing initial acquisition information to the DSIF tracking stations. These calculations are performed on an IBM 7094 computer located at AFETR using *Agena* vehicle tracking data obtained from the downrange AFETR tracking stations. Results of these calculations are transmitted to the JPL SFOF in Pasadena. The acquisition information is relayed to the DSIF stations, and the initial orbital elements are used in the JPL orbital calculations.

In addition to fulfilling these requirements, AFETR transmits tracking data obtained during the parking orbit, transfer orbit, and *Agena* postretro orbit to the SFOF. The parking orbit data are very useful for detecting nonstandard flight conditions, and the transfer orbit data are used during flight operations to verify the initial orbital estimates based on DSIF data. *Agena* postretro data are important for verifying *Agena* retrofiring, and are further used to establish the *Agena* vehicle postretro orbit.

During this mission, AFETR stations tracked the *Ranger VII Agena* vehicle from launch until it was lost by Pretoria 8 min after *Agena* retrofiring. Additional tracking data were supplied by two National Aeronautics and Space Administration (NASA) stations located at Bermuda and Carnarvon, Australia. The names, locations, and radar types for the AFETR and NASA stations are given in Table 32. Table 33 summarizes the tracking data coverage provided by these stations.

B. Acquisition Information

Twenty-four minutes of initial acquisition information was provided for DSIF Stations 41, 51, and 59, based on the actual parking orbit and nominal second *Agena* burn. Shortly after injection, this information was updated for 100 min, based on the actual transfer orbit. These predictions included pointing angles, receiver doppler detector output for both one-way and two-way doppler, and the ground station transmitter reference frequency required to establish uplink lock with the spacecraft. A comparison between the AFETR predicted pointing angles and the actual tracking angles showed that the predicted values were well within the beam width of all station antennas.

Table 32. AFETR and NASA station locations[a]

C. *Analysis of Parking Orbit Data*

In the parking orbit phase, angular and range data were obtained by Antigua, Ascension and Bermuda. During flight operations, only Antigua data were used for the parking orbit calculation made at JPL. Numerical values for the parameters in this solution are given in Table 34, column 3. These values are in good agreement with orbital elements obtained from the AFETR solution seen in column 2, except for Ω (longitude of ascending node) and ω (argument of pericenter passages). Table 35 shows the number of data points and associated statistics for this calculation. The residuals, observed minus computed, may be seen in Fig. 50.

For the postflight analysis an orbital estimate was made using data from Ascension and Bermuda only. The data points used and the associated statistics are given in Table 36. Bermuda angular data were not used for this calculation, and it was necessary to correct the ranging data values to account for range reference oscillator timing errors.[13] The number of points and the associated statistics are given in Table 36, and the residual plots may be seen in Figs. 51 and 52. Parameter values, given in Table 34, column 4, show good agreement with the two real-time orbital solutions seen in columns 2 and 3 of the Table. The solutions for argument of pericenter passage do not appear consistent. However, this parameter is not well defined for this orbit due to the near zero values for both the eccentricity e and path angle γ_0. Using these data, the latitude and longitude of the Bermuda tracking station were determined. This solution

Table 34. Parking orbit parameter solutions (Epoch = 16 hr 58 min 32.00 sec)

Orbital parameter	Orbit reported by ETR[a] (2)	Real time orbit[b] (3)	Post analysis orbit[c] (4)

[b]Orbit from Antigua data only (calculated at JPL).

[c]Orbit from Bermuda and Ascension (calculated at JPL).

Note: the ETR orbit is received prior to obtaining the solution shown in column 3.

Table 35. Inflight parking orbit data statistics

Station name	Data type	Number of points used	Standard deviation	Mean
Antigua	Range, m	15	5	16.1
	Azimuth, deg	23	0.0080	0.0000
	Elevation, deg	23	0.0437	0.0202

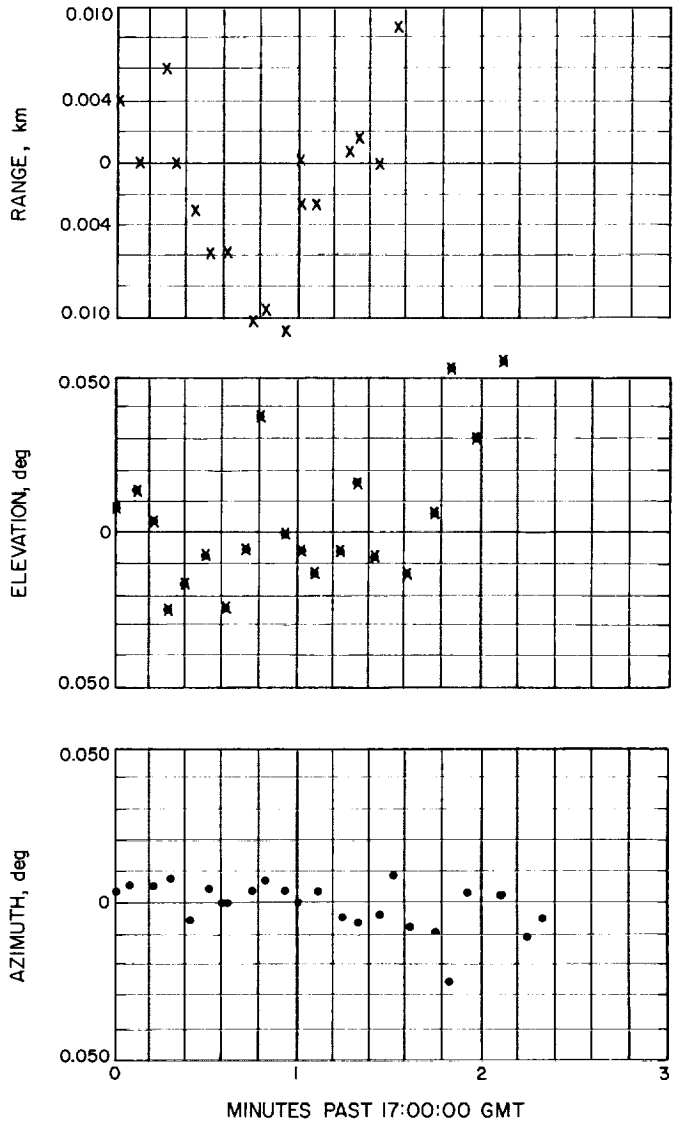

Fig. 50. Antigua parking orbit residuals

[13]This type of error is apparently a characteristic of the C-band pulse radar systems used by these AFETR and NASA stations (Ref. 16).

Table 36. Postflight parking orbit data statistics

Station name	Data type	Number of points used	Standard deviation	Mean
Bermuda	Range, m	20	16	2.85
Ascension	Range, m	32	7	1.53
	Azimuth, deg	32	0.0187	0.0000
	Elevation, deg	31	0.0185	0.0031

shows good agreement with the solution obtained during the *Ranger VI* mission. These results may be seen in Table 37.

When a combined orbital calculation was made using data from all three stations, the Antigua data appeared to be somewhat inconsistent with the data from the other two stations. This is still being investigated.

	Elevation, deg	65	0.0091	−0.00381

D. *Analysis of Agena Preretro Transfer Orbit Tracking Data*

Preretro tracking data were received from Pretoria from 17:21:30 to 17:29:06 GMT July 28. These data were used during flight operations to determine the *Agena* transfer orbit. This solution agreed very well with the transfer orbit solution previously reported by AFETR. In addition, portions of the Pretoria data were used in the JPL orbital calculations to verify the initial orbit estimates based on DSIF data.

In the postflight analysis, a comparison between the best postflight estimate of the premaneuver orbit based on DSIF data only and the estimate based on the Pretoria data showed the two solutions to be in remarkably good agreement. The values of the parameters for these solutions may be seen in Table 38, columns 2 and 3. Tracking data statistics for the Pretoria estimate are given in Table 39, and the residual plots may be seen in Figs. 53 and 54.

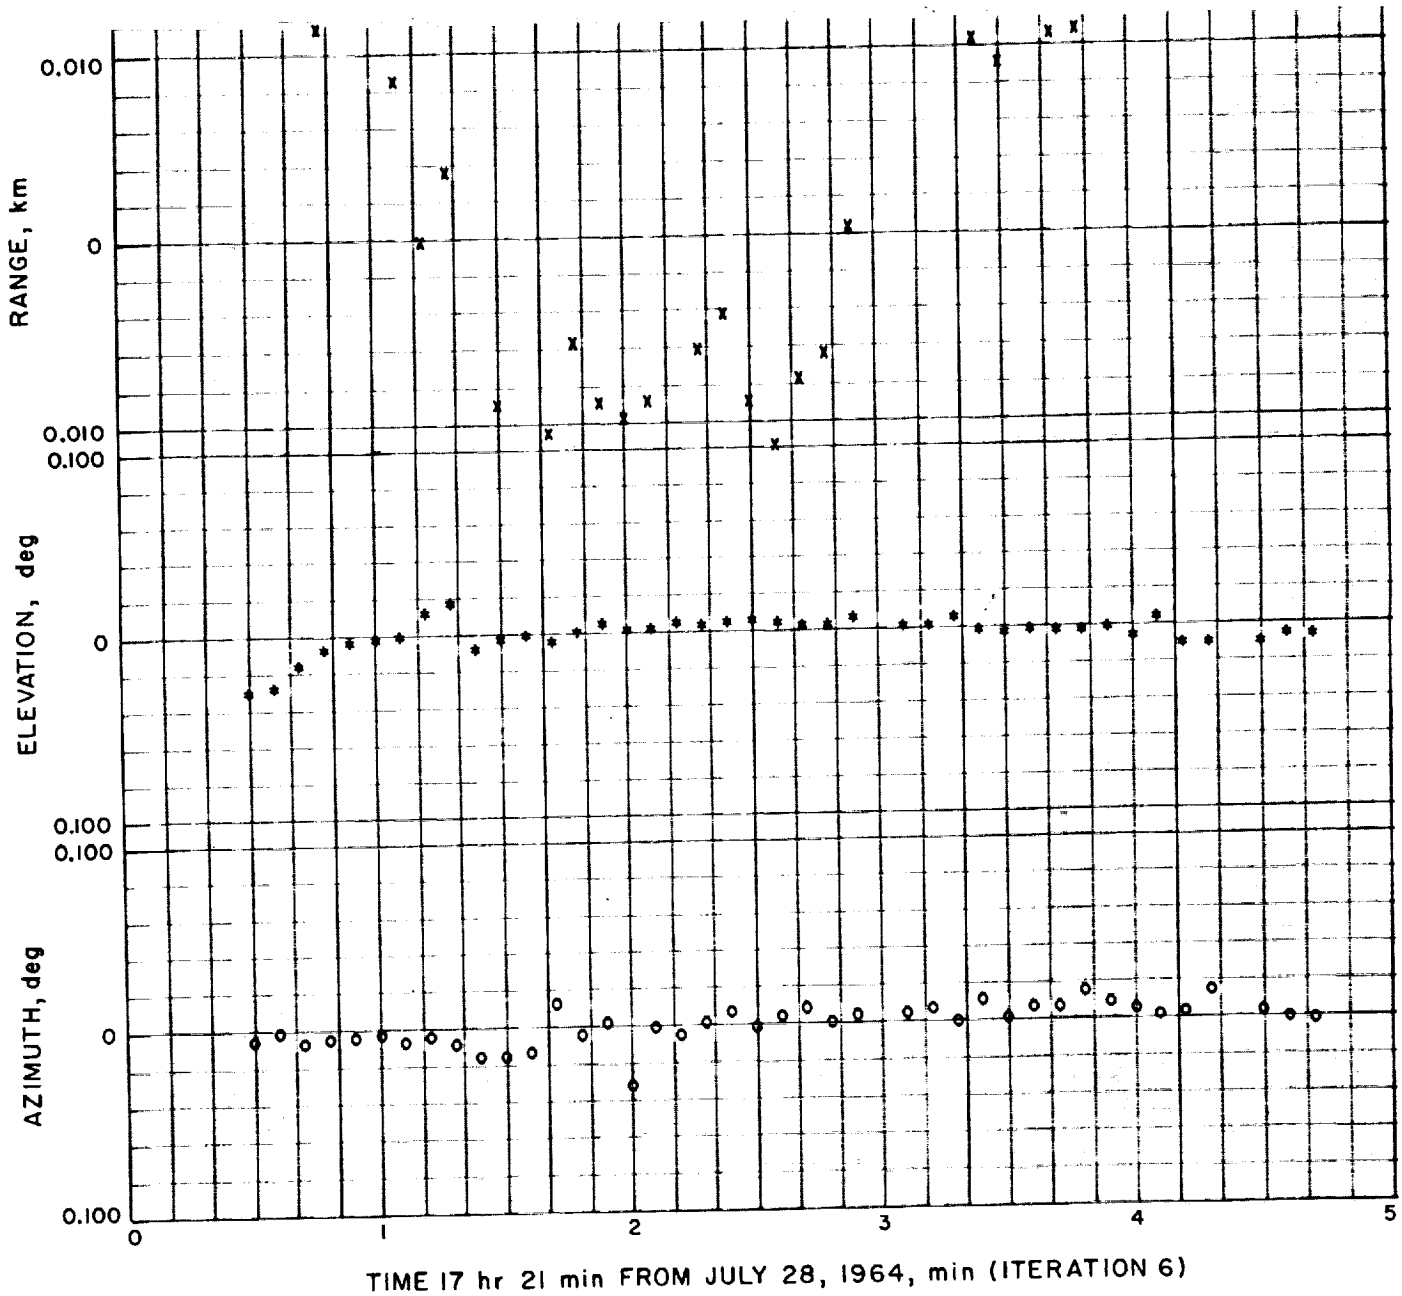

Fig. 53. Pretoria preretro residuals (start 17:21 GMT)

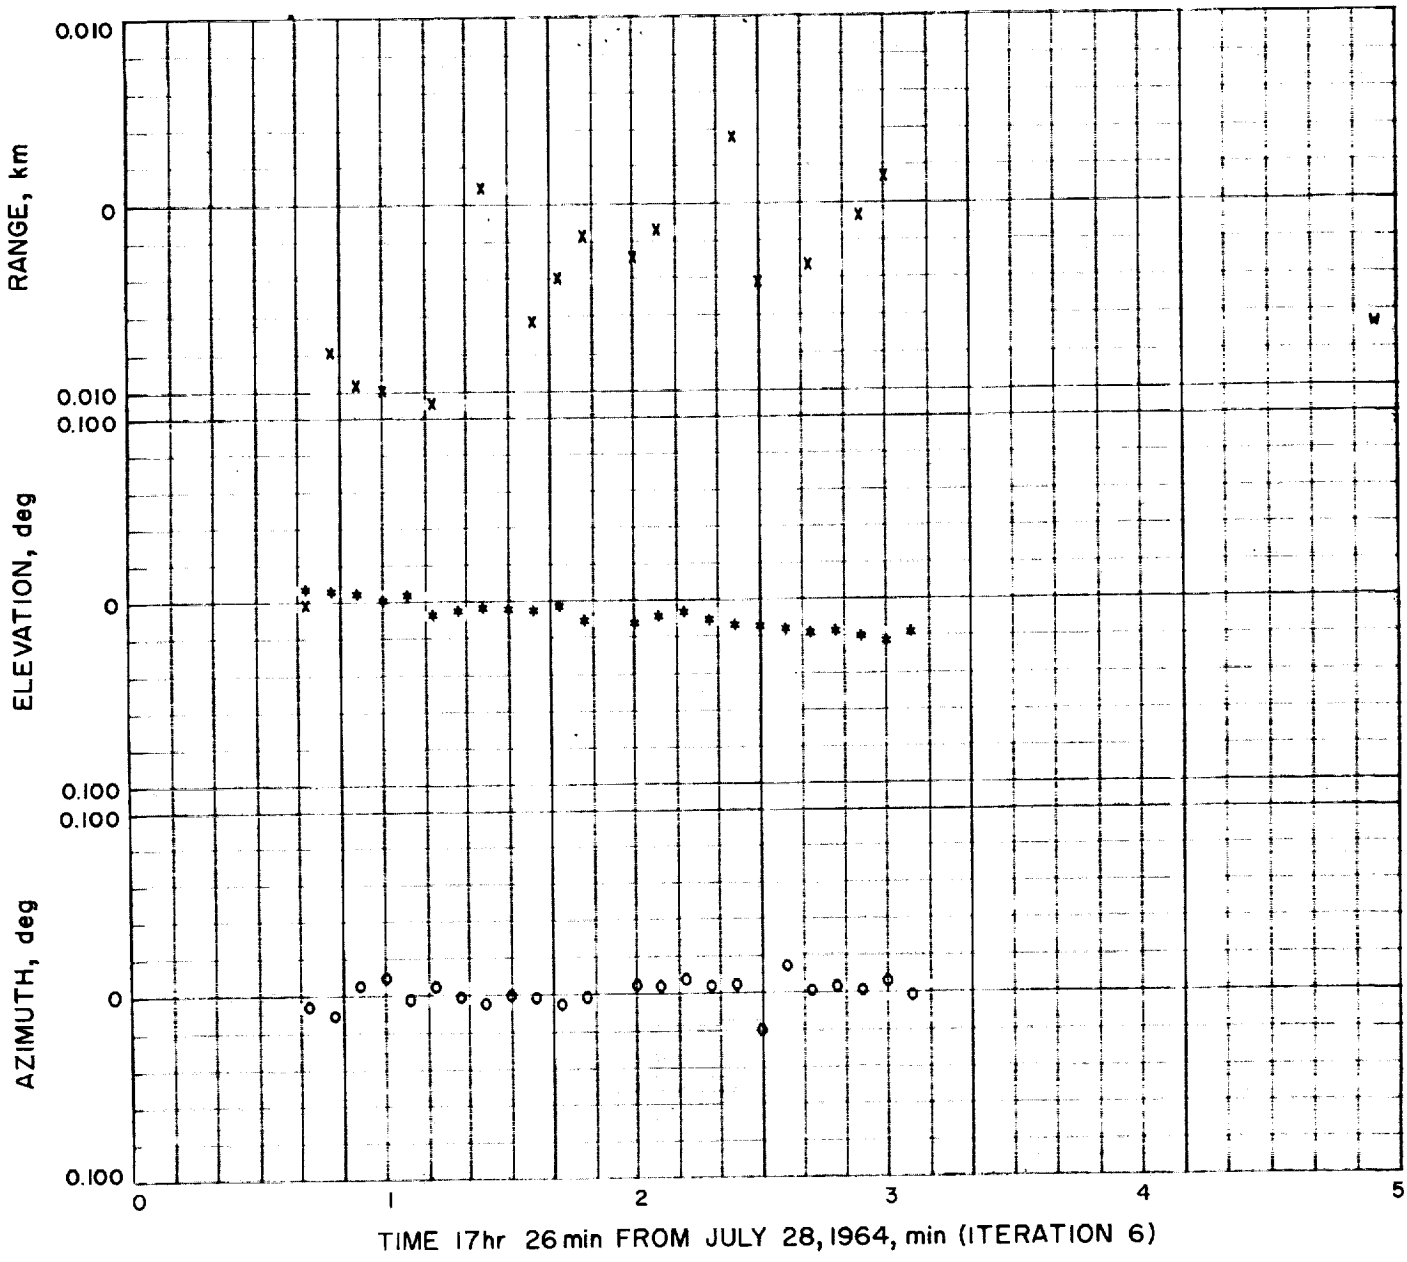

Fig. 54. Pretoria preretro residuals (start 17:26 GMT)

E. Analysis of Agena Postretro Tracking Data

Agena postretro tracking data were received from Pretoria and Carnarvon. An estimate of the *Agena* postretro orbit was made using only Pretoria data. This solution revealed that the *Agena* vehicle would miss the Moon's surface by 3660 km and go into a heliocentric orbit. Parameter values for this estimate are given in Table 38, column 4. The number of points and associated statistics are given in Table 40, and the residual plots may be seen Figs. 55 and 56.

Table 40. Postretro orbit data statistics

Station name	Data type	Number of points used	Standard deviation	Mean
Pretoria	Range, m	25	38	1.17
	Azimuth, deg	45	0.0143	0.0000
	Elevation, deg	45	0.0299	−0.0150

A combined estimate based on both Pretoria and Carnarvon data has not yet been satisfactorily made (apparently due to an error in the station coordinates at Carnarvon). The Carnarvon data appeared to be relatively noise free, but a good estimate of the data accuracy is not possible at this time.

F. Conclusions

The Pretoria tracking data were very useful during flight operations for verifying the initial orbit estimates based on DSIF data. It is anticipated that these data will be more fully utilized in conjunction with the DSIF data as continued confidence is obtained from flight experience.

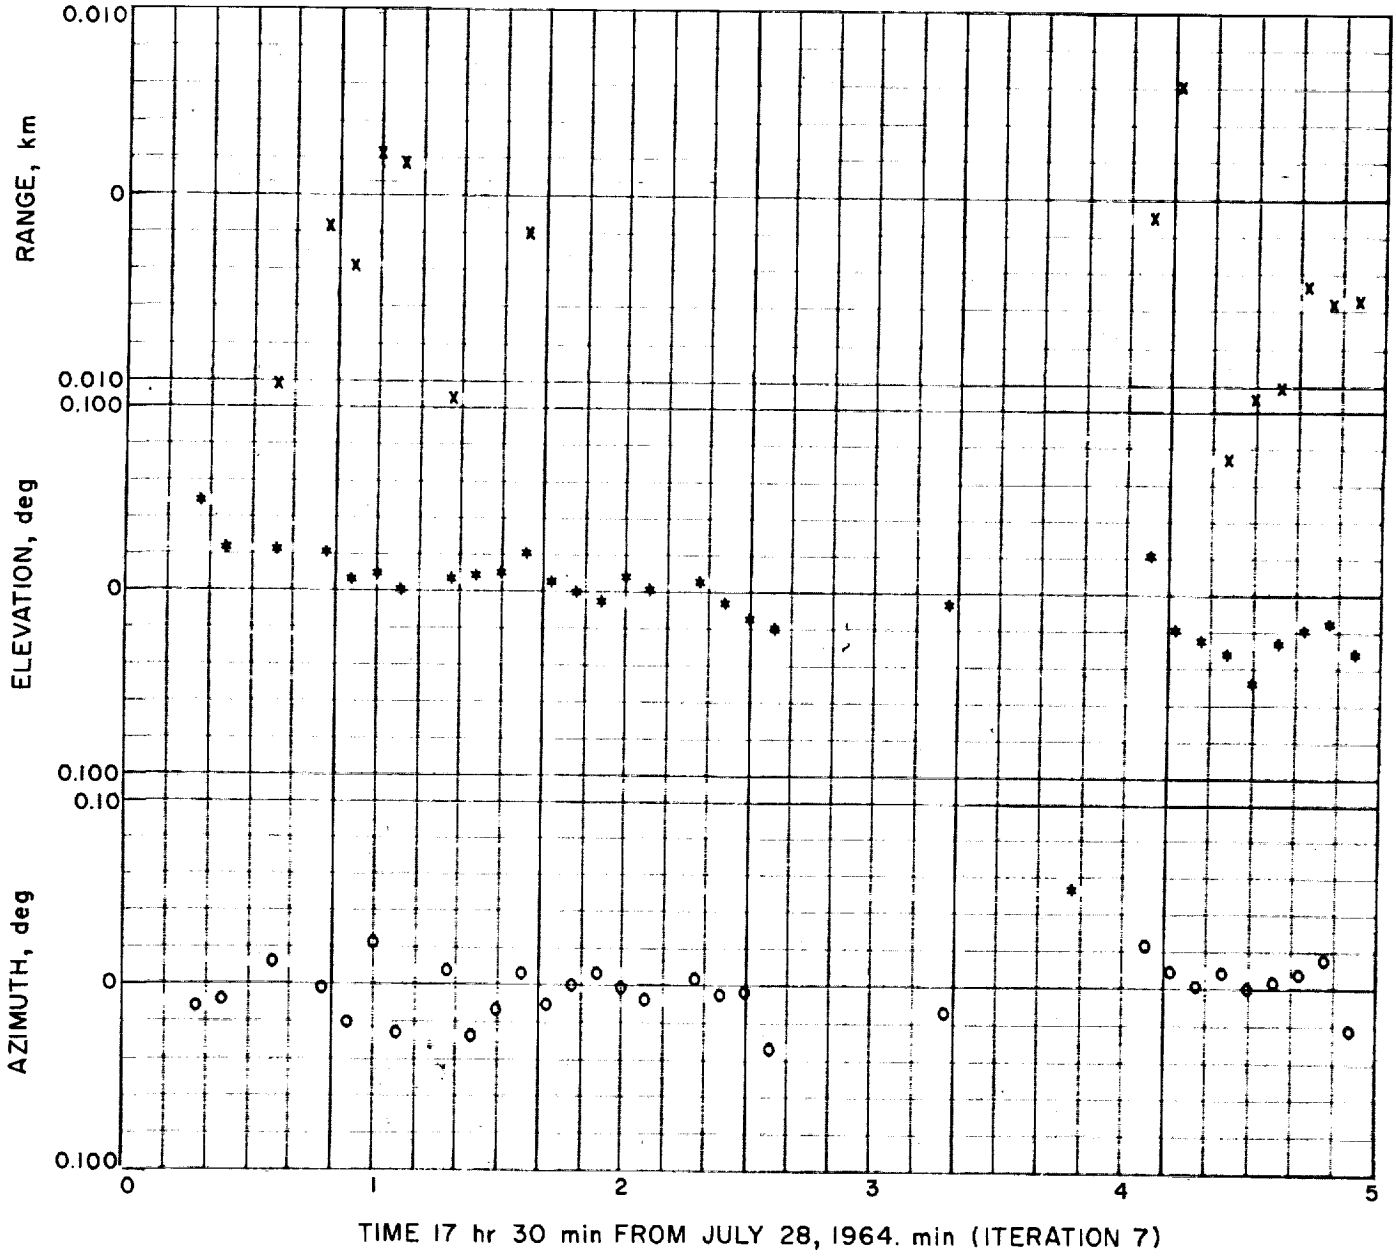

Fig. 55. Pretoria postretro residuals (start 17:30 GMT)

VI. DEEP SPACE INSTRUMENTATION FACILITY TRACKING OF *RANGER VII*

A. General Information

The DSIF is primarily composed of various tracking stations located around the world and interfaces which connect these tracking stations with the main control center at JPL. The names and locations of the DSIF stations employed in the *Ranger VII* mission are given in Table 41. Since Station 71, located at Cape Kennedy, does not obtain postinjection tracking data, it is not listed in Table 41. This station performs the vital task of prelaunch checkout of the spacecraft radio, telemetry, and TV systems. It also provides spacecraft frequencies to the Tracking Data Analysis Group at the SFOF for use in computing acquisition predictions. Detailed characteristics of the stations are available elsewhere.[14]

Table 42 shows the nominal view periods of the spacecraft to the DSIF stations during the course of the mission. Rise and set times (in GMT) refer to that time at which the spacecraft is at a 5-deg geometrical elevation angle. Since the spacecraft signal can frequently be received when the spacecraft is lower than 5 deg, it is possible that acquisition of the spacecraft will occur before nominal rise time and loss of signal after nominal set time. The modes of operation of the DSIF are identified as ground modes (GM) and can be seen in Table 43.

Table 41. DSIF station locations

Station	Location	Geodetic latitude, deg	Astronomic longitude, deg
12	Goldstone, California	35.4 N	116.8 W
41	Woomera, Australia	31.4 S	136.9 E
51	Johannesburg, South Africa	25.9 S	27.7 E
59	Johannesburg, South Africa	25.9 S	27.7 E

During *Ranger VII*, the DSIF stations provided both angular and doppler data throughout the mission. Both data types were used during the early part of the mission, and the angular data were very useful in obtaining the initial orbit estimates. For the postflight analysis, only two-way doppler data were used. Plots of the doppler residuals for both premaneuver and postmaneuver tracking may be seen in Figs. 8 through 24. Relatively large biases were seen in the angular data from Stations 41 and 51. This is mainly due to angular correction model errors which, in turn, were caused by recent extensive equipment changes and RF feed realignment at the angle tracking stations. New correction coefficients are being determined to remove these biases during future missions.

[14] Jet Propulsion Laboratory, *Space Flight Operations Plan, Ranger VII*, May 28, 1964 (internal communication).

Table 42. Nominal[a] view periods vs actual tracking at DSIF stations

Date	DSIF Station	Nominal rise, GMT	Nominal set, GMT	Nominal view period	Acquisition by Station	Loss of signal by Station	Actual view period

[a] Based on 5-deg elevation angle.
[b] Set occurs on day after rise.
[c] Time of lunar impact.

Table 43. Ground station tracking modes

This mode description is used to define the station configuration. The code is broken into two parts. The first defines the transmit/receive mode and the second the antenna feed configuration.

Transmit/receive		Antenna feed	
GM-0[a]	No receive (transmit only)	0	Not used
GM-1	One-way doppler (receive only)	1	Horn feed diplexer combination (85-ft D reflector)
GM-2	Two-way, one-station (transmit/receive)	2	Tracking feed diplexer combination (85-ft D reflector)
GM-3	Two-way, two-station noncoherent (receive only)	3	Acquisition antenna
GM-4	Two-way, two-station coherent (receive only with reference signal from transmit station)	4	Dipole (6-ft D reflector)
GM-5	Receive only (no doppler)	5	Horn feed, no diplexer (receive only) (85-ft D reflector)

[a]Telemetry will be available in all receive modes except GM-0.
Example: GM-2-1; transmitting to spacecraft and receiving two-way doppler; horn feed and diplexer.

B. Transponder Tracking

1. Premaneuver Phase

Initial acquisition of the spacecraft transponder was made by Station 59 at 17:20:50 GMT on July 28, 1964. Two-way lock was immediately established and the servo system was put in auto track at 17:21:00. Auto track was terminated at 17:21:39 and the receiver dropped lock at 17:23:12. From this time until the end of the pass at 17:37:53, the receiver was unable to maintain continuous lock, primarily due to high spacecraft angular rates and operational procedure difficulties. From this pass only five 5-sec count two-way doppler points were usable in the ODP. At 17:28:07 Station 51 switched on their transmitter, and two-way lock was established at 17:30:14. Station 51 also experienced difficulty in maintaining continuous receiver lock due to high angle rates, and the antenna reached its mechanical limit at 17:31:42. During this interval, no good two-way doppler samples were obtained.

At 17:38:48, Station 41 achieved two-way lock in GM-2-2. They did not get any good doppler samples until 17:54:00 because of an overloaded counter monitoring the doppler mixer output. This situation arose as a direct result of a changed configuration in the L-band receiver following L–S band conversion work and was easily corrected when discovered. Telemetry event blips B-2-1 through B-2-4 observed by Station 41 starting at 17:50:00 indicated that solar panel extension had occurred. At 17:53:00 a B-2-1 blip was observed which indicated the start of the Sun acquisition sequence. Earth acquisition event blip was noted by Stations 41 and 51. The first ground station command sequence was transmitted to the spacecraft by Station 41, commencing at 21:15:00. Two "clear" commands were sent followed by an antenna switchover command which switches the spacecraft from the low gain omniantenna to the high gain directional antenna. During the mutual view period of Stations 41 and 51, transfers of two-way lock were executed three times. The first transfer, from Station 41 to 51, occurred at 21:58:00. The second transfer, from Station 51 to 41, occurred at 23:10:00. The third and last transfer of this pass, from Station 41 to 51, occurred at 24:00:00. Tracking continued without incident until the maneuver phase began on July 29.

2. Maneuver Phase

At 08:50:00 July 29, Station 12 started transmitting the midcourse maneuver command sequence. At 09:40:00 Station 12 transmitted the antenna changeover command which switched the spacecraft back to the low gain omniantenna, and at 10:00:00 the maneuver execute command was transmitted. At 10:27:09, after the programmed delay, an event blip was observed which indicated midcourse motor ignition. This was immediately followed by a decrease in received doppler frequency, as predicted. The decrease continued until motor cutoff, and then the observed doppler started to rise slightly, again as predicted. A plot showing predicted doppler and observed doppler during the maneuver period may be seen in Fig. 57.

3. Postmaneuver Phase

Following the maneuver, the spacecraft reacquired the Sun at 10:36:00, and the Earth at 10:58:39. At 11:21:00 Station 12 started transmitting the command sequence to switch the spacecraft back to the high gain antenna. Transponder tracking then continued in a normal manner with a minimum amount of data being lost when transferring from one station to another. At 11:15:30 on July 31, Station 12 began transmitting a terminal maneuver command sequence. While an orientation maneuver was not required, a terminal maneuver sequence was commanded to set an additional backup timer for the TV system. The terminal maneuver was then inhibited by

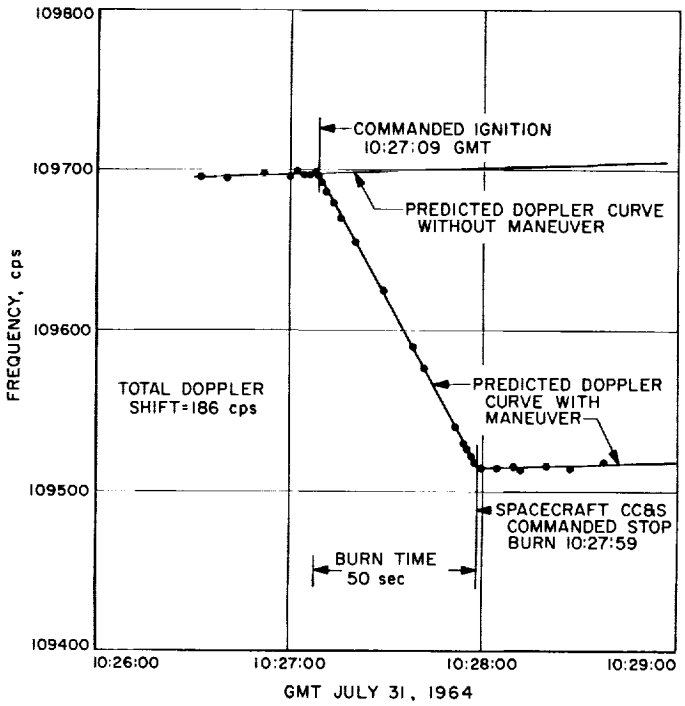

Fig. 57. Doppler during midcourse maneuver

an override command transmitted at 11:55:00. The terminal maneuver execute command was transmitted at 12:25:08. Subsequent event blips indicated that the spacecraft responded properly. At 13:08:40 Channel F video appeared, and at 13:12:07 Channel P video went to full power. From 13:12:08 until impact, Station 12 was receiving excellent photographs of the lunar surface. A summary of all commands transmitted to the spacecraft by the DSIF is given in Table 44.[15]

C. *Determination of Impact Time*

The primary method of determining observed impact time is by measuring the time at which the spacecraft signal is lost. Various functions related to the spacecraft signal are continuously recorded by the stations during their respective tracking periods. Two recording methods are used: one is magnetic tape, and the other is direct-write oscillograph.

Stations 11[16] and 12 were tracking the spacecraft on July 31 when an abrupt loss of signal occurred at approximately 13:25:50. Figure 58 shows the *unfiltered* received signal strength recorded at Station 12 at lunar encounter. High speed recording rate (approximately 60 in./sec) was not used until shortly before predicted impact. This recording was referenced by a 100 pps timing reference and the NASA 28-bit time code which is synchronized to WWV. At the time noted by the arrow in Fig. 58 (13:25:50.029), the transponder signal was lost. Figure 59 is a playback of the receiver functions recorded on magnetic tape at Station 12 starting just prior to impact. The drastic changes seen in the telemetry channels (the traces labeled Channel 2 and Channel 3) provide further confidence that impact occurred at the time noted by the abrupt change in received signal strength.

[15]Jet Propulsion Laboratory, *Tracking Operations Memorandum, Ranger VII*, September 21, 1964 (internal communication).

[16]Station 11 was committed to provide TV backup support only. They tracked the spacecraft only during the last Goldstone view period, but did not obtain tracking data.

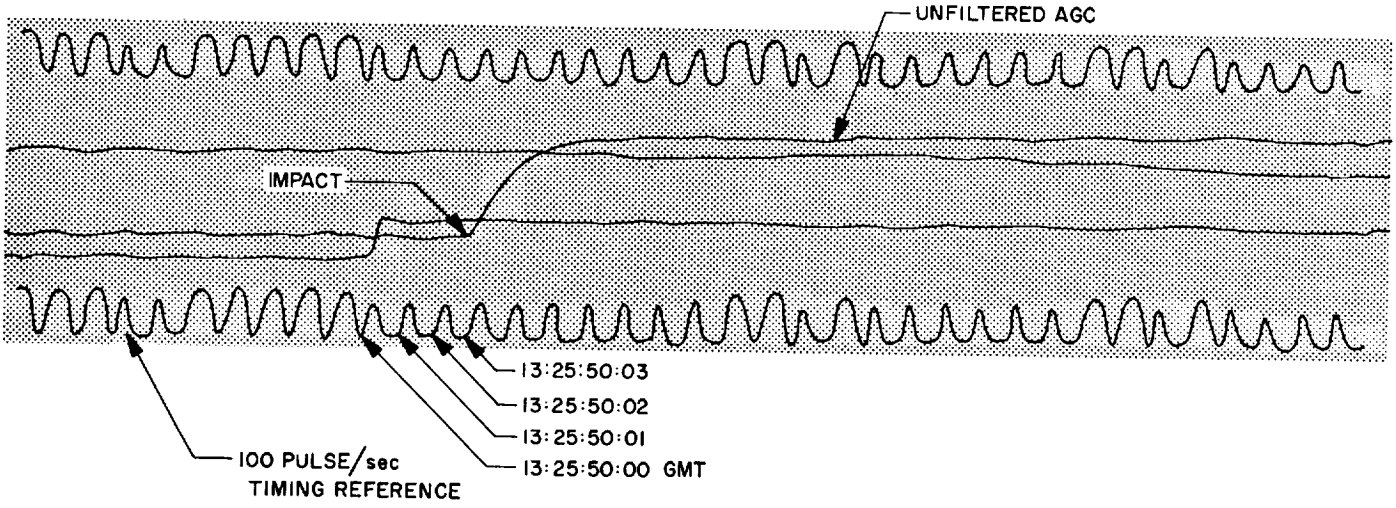

Fig. 58. Station 12 impact recording

Figure 60 is a playback of the magnetic tape recorded at Station 11. In this Figure, no abrupt change in the received signal strength can be seen at the impact time indicated by the drastic change in the telemetry channel traces. This is due to the fact that the receiver automatic gain control (AGC) time constant was set at 300 sec. The best estimate of impact time observed at Station 11 is 13:25:50.095. It will be noted that there is a 66-msec difference between the impact times recorded at the two Stations. After postflight analysis of station operations at Stations 11 and 12 in regard to this discrepancy, it was concluded that: (1) Station 11 impact time is incorrect because of a time synchronization problem at Station 11, and (2) the impact time recorded at Station 12 is correct. This large discrepancy should not be considered a measure of the system accuracy since in *Ranger VI*, when Stations 11 and 12 were committed for full mission support, the impact times recorded at the two Stations agreed to within 1 msec.

The conclusion is that, neglecting signal transit time, *Ranger VII* impacted the Moon at 13:25:50.029 +0.02 or −0.03 sec.

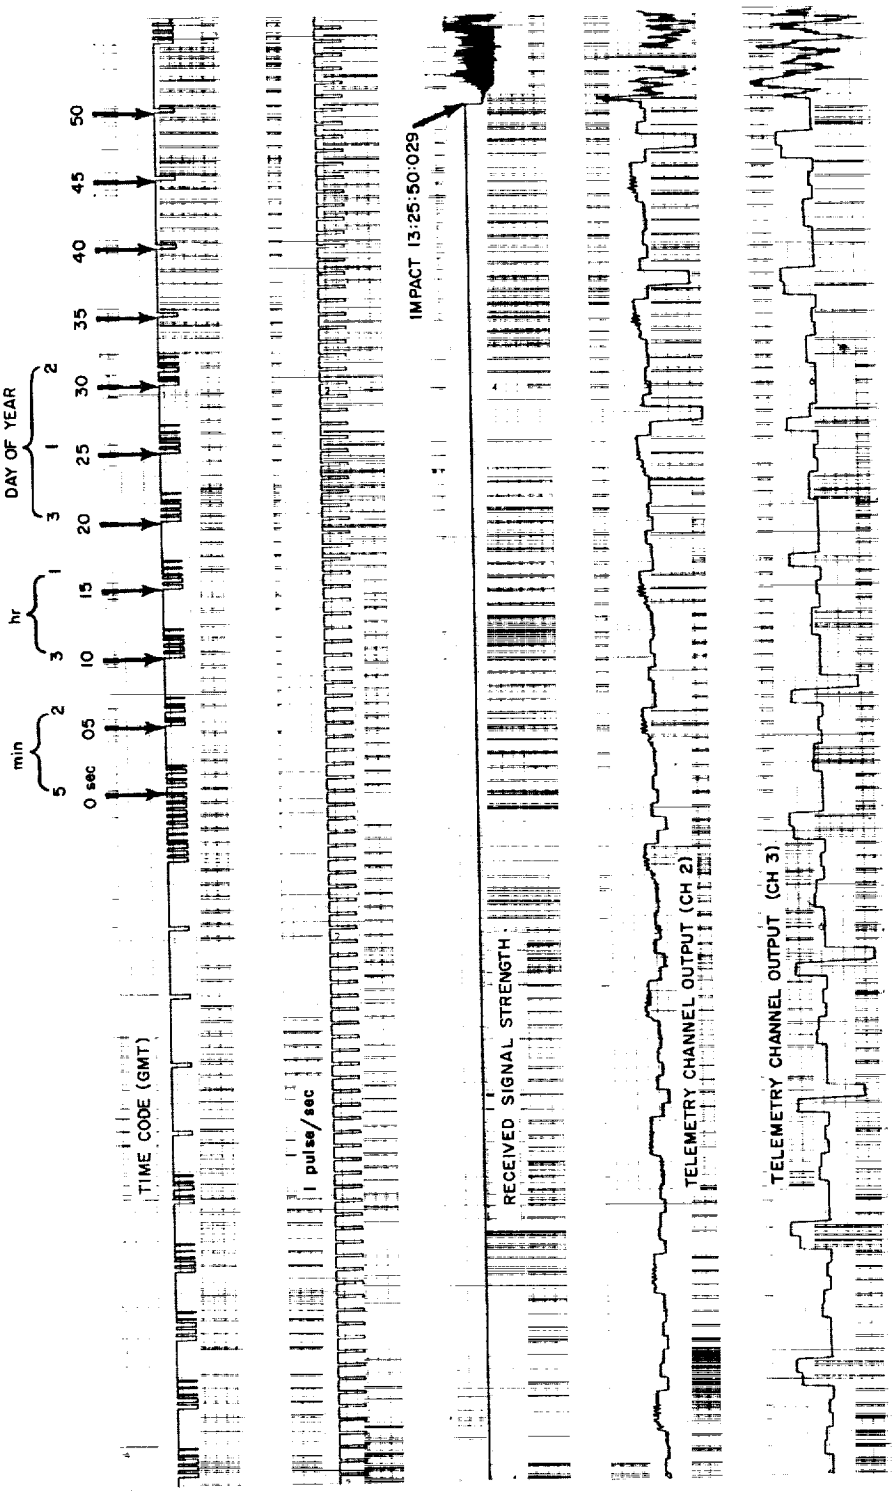

Fig. 59. Station 12 analog of selected receiver functions at lunar impact

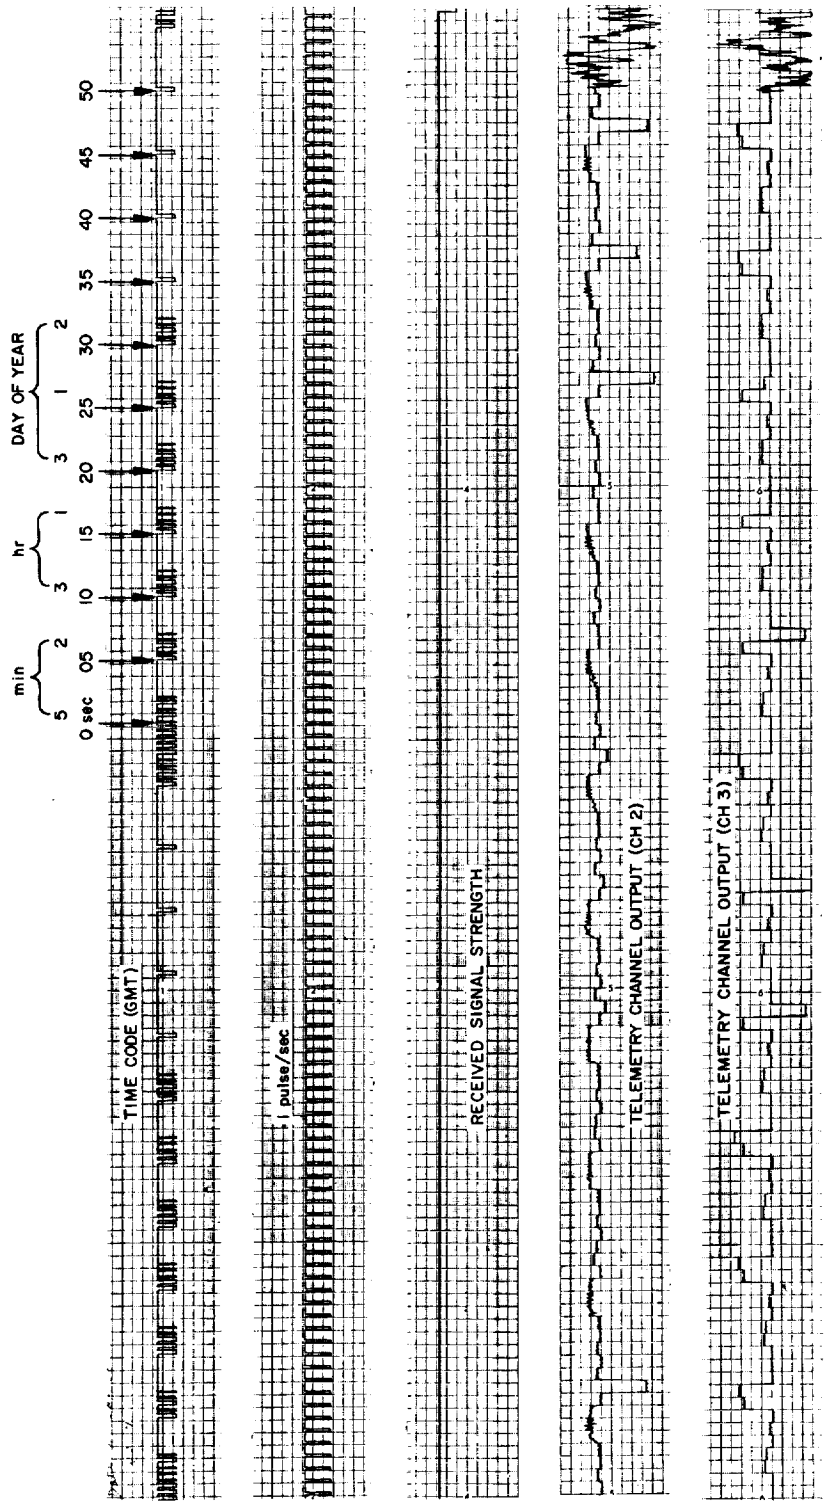

Fig. 60. Station 11 analog of selected receiver functions at lunar impact

APPENDIX A

Definition of the miss parameter B

The miss parameter **B** is used at JPL to measure miss distances for lunar and interplanetary trajectories and is described by W. Kizner in Ref. 6. **B** has the desirable feature of being very nearly a linear function of changes in injection conditions.

The osculating conic at closest approach to the target body is used in defining **B**. **B** is the vector from the target's center of mass perpendicular to the incoming asymptote. Let $\mathbf{S}_I$ be a unit vector in the direction of the incoming asymptote. The orientation of **B** in the plane normal to $\mathbf{S}_I$ is described in terms of two unit vectors **R** and **T**, normal to $\mathbf{S}_I$. **T** is taken parallel to a fixed *reference plane* and **R** completes a right-handed orthogonal system. Figure A-1 illustrates the situation.

The *Ranger VII* work has used the orbital plane of the Moon as the reference plane. If **W** is a unit vector normal to the orbital plane (**W** in direction of $\mathbf{R}_M \times \mathbf{V}_M$, where $\mathbf{R}_M$ is radius vector to Moon from Earth, and $\mathbf{V}_M$ is the space-fixed velocity of the Moon relative to the Earth's center), then $\mathbf{T} = \mathbf{S}_I \times \mathbf{W}$ defines our coordinate system.

Table D-2. *Ranger VII* trajectory key definitions

Group A		
Row 1	GME	Universal gravitational constant times the mass of Earth, km^3/sec^2
	J	Coefficient of the second harmonic in the Earth's potential function
	H	Coefficient of the third harmonic in the Earth's potential function
	D	Coefficient of the fourth harmonic in the Earth's potential function
	RE	Earth radius used in the potential function, km
	REM	Conversion factor for converting lunar ephemerides into km
Row 2	G	Universal constant of gravitation, $km^3/kg\ sec^2$
	A, B, C	Moments of inertia about principal axis for the Moon, $kg\ km^2$
	OME	Sidereal rotation rate of the Earth, deg/sec
	AU	Astronomical unit, km
Row 3	GMM	Universal gravitational constant times the mass of Moon, km^3/sec^2
	GMS	Universal gravitational constant times the mass of Sun, km^3/sec^2
	GMV	Universal gravitational constant times the mass of Venus, km^3/sec^2
	GMA	Universal gravitational constant times the mass of Mars, km^3/sec^2
	GMB	Universal gravitational constant times the mass of Earth–Moon, km^3/sec^2
	GMJ	Universal gravitational constant times the mass of Jupiter, km^3/sec^2
Row 4	EGM	Universal gravitational constant times the mass of Earth used for scaling ephemeris, km^3/sec^2
	MGM	Universal gravitational constant times the mass of Moon used for scaling ephemeris, km^3/sec^2
	JA	Coefficient of second harmonic in Mars potential function
	RA	Mars radius used in the potential function
Row 5	ARA	Frontal area of spacecraft, m^2
	GB	Multiple of % of reflected radiant energy
	MAS	Mass of spacecraft, kg
	SC	Solar radiation constant $(kg\text{-}km/sec^2)\ 10^{-6}$
Group B		Injection conditions are vernal equinox Cartesian coordinates in a geocentric equatorial system. The principal direction X is the vernal equinox direction of date, and the principal plane XY is the equatorial plane of date. Z is along the direction of the Earth's spin axis of date.
Row 6	XO, YO, ZO	Cartesian components of the probe radius vector, km
	DXO, DYO, DZO	Cartesian components of the probe space-fixed velocity vector, km/sec
Row 7	TO	Time of injection in seconds past midnight of day before launch, sec
	GHA	HA of Greenwich at injection epoch, deg
	GHO	HA of Greenwich at midnight of day before launch, deg
Group C		Inertial position and velocity of the probe, Sun, Moon and target body in a geocentric equatorial system. The principal direction X is the vernal equinox direction of date, and the principal plane XY is the equatorial plane of date. Z is along the direction of the Earth's spin axis of date. Miscellaneous parameters are also included.
Row 8	X, Y, Z	Cartesian components of the probe radius vector, km
	DX, DY, DZ	Cartesian components of the probe space-fixed velocity vector, km/sec
Row 9	R	Probe radius distance, km
	DEC	Probe declination angle, deg
	RA	Probe right-ascension angle, deg
	V	Probe space-fixed velocity, km/sec
	PTH	Pitch angle of the probe space-fixed velocity vector with respect to the local horizontal, deg
	AZ	Azimuth angle of the probe space-fixed velocity vector measured East of true North, deg

Table D-2. *Ranger VII* trajectory key definitions (Cont'd)

Row 10*	R	Probe radius distance, km
	LAT	Probe geocentric latitude, deg
	LON	Probe East longitude, deg
	VE	Probe Earth-fixed velocity, km/sec
	PTE	Pitch angle of the probe Earth-fixed velocity vector with respect to the local horizontal, deg
	AZE	Azimuth angle of the probe Earth-fixed velocity vector measured East of true North, deg
Row 11	XS, YS, ZS	Cartesian components of the Sun radius vector, km
	DXS, DYS, DZS	Cartesian components of the Sun space-fixed velocity vector, km/sec
Row 12	XM, YM, ZM	Cartesian components of the Moon radius vector, km
	DXM, DYM, DZM	Cartesian components of the Moon space-fixed velocity vector, km/sec
Row 13	XT, YT, ZT	Cartesian components of the target radius vector, km
	DXT, DYT, DZT	Cartesian components of the target space-fixed velocity vector, km/sec
Row 14	RS	Sun radius distance, km
	VS	Sun space-fixed velocity, km/sec
	RM	Moon radius distance, km
	VM	Moon space-fixed velocity, km/sec
	RT	Target radius distance, km
	VT	Target space-fixed velocity, km/sec
Row 15	GED	Geodetic latitude of the probe, deg
	ALT	Altitude of the probe above the Earth's surface, km
	LOS	East longitude of the Sun in coordinate system defined in Row 10, deg
	RAS	Right ascension of the Sun, deg
	RAM	Right ascension of the Moon, deg
	LOM	East longitude of the Moon in coordinate system defined in Row 10, deg
Row 16	DUT	Ephemeris time minus Universal Time, sec
	DT	Adams–Moulton step size, sec
	DR	Radial velocity of probe, km/sec
	SHA	Sun shadow parameter, km
	DES	Declination of the Sun, deg
	DEM	Declination of the Moon, deg
Group D		General characteristics of the geocentric conic
Row 17	SMA	Semimajor axis, km
	ECC	Eccentricity
	B	Magnitude of the impact parameter,** km
	SLR	Semilatus rectum, km
	APO	Apogee distance, km
	RCA	Magnitude of the closest approach vector, km
Row 18	VH	Hyperbolic excess speed, km/sec
	C3	Twice the energy (*vis viva* energy integral, km^2/sec^2)
	C1	Angular momentum, km^2/sec
	TFP	Time from pericenter passage, sec
	TF	Time from injection to pericenter passage, hr
	PER	Period, min
Row 19	TA	True anomaly, deg
	MTA	Maximum true anomaly, deg
	EA	Eccentric anomaly, deg
	MA	Mean anomaly, deg
	C3J	Earth–Moon Jacobi constant, km^2/sec^2
	TFI	Time from injection, hr
Group E		Characteristics of the Earth conic in the geocentric equatorial system described under Group B
Row 20	X, Y, Z	Cartesian components of the probe radius vector, km
	DX, DY, DZ	Cartesian components of the probe space-fixed velocity vector, km/sec
Row 21	INC	Inclination of the orbit plane to the equatorial plane, deg
	LAN	Longitude of the ascending node, deg
	APF	Argument of pericenter, deg

*These are Earth-fixed spherical coordinates in a geocentric equatorial system. The principal direction X is directed toward Greenwich and is the intersection or the meridian plane of Greenwich with the equatorial plane. The principal plane is the Earth's geometrical equatorial plane. X, Y, Z is along the direction of the Earth's geometrical North direction.

**See Appendix A.

Table D-2. *Ranger VII* trajectory key definitions (Cont'd)

Row 21 (Cont'd)	MX, MY, MZ	Components of a unit vector which lies in the orbit plane and is normal to the radius vector **R** $\mathbf{M} = \mathbf{W} \times \frac{\mathbf{R}}{\lvert\mathbf{R}\rvert}$
Row 22	WX, WY, WZ	Components of a unit vector normal to the conic $\mathbf{W} = \frac{\mathbf{R} \times \mathbf{V}}{\lvert\mathbf{R} \times \mathbf{V}\rvert}$
	PX, PY, PZ	Components of a unit vector in the direction of perigee
Row 23	QX, QY, QZ	Components of a unit vector perpendicular to the perigee direction, vector **P**, and being in the orbit plane $\mathbf{Q} = \mathbf{W} \times \mathbf{P}$
	RX, RY, RZ	Components of the unit vector **R****
Row 24	BX, BY, BZ	Components of the impact parameter **B**,** km
	TX, TY, TZ	Components of the unit vector **T****
Row 25	DAP	Declination of the asymptote, deg
	RAP	Right ascension of the asymptote, deg
Row 26	BTQ	Projection of the impact parameters **B**** upon the vector **T**, km
	BRQ	Projection of the impact parameters **B**** upon the vector **R**, km
	B	The magnitude of the impact parameter,** km
	THA	Angle between the parameter **B**** and the vector **T** measured clockwise from **T**, deg
Group F		Inertial position and velocity of the probe, Sun, Moon, and target body in a heliocentric equatorial system. The principal direction X is the vernal equinox direction of date and the principal plane XY is the equatorial plane of date. Z is along the direction of the Earth's spin axis of date. Miscellaneous parameters are also included.
Row 27	X, Y, Z	Cartesian components of the probe radius vector, km
	DX, DY, DZ	Cartesian components of the probe space-fixed velocity vector, km/sec
Row 28	R	Sun–probe radius distance, km
	LAT	Probe celestial declination, deg
	LON	Probe celestial right ascension, deg
	V	Probe space-fixed velocity, km/sec
	PTH	Pitch angle of the probe space-fixed velocity vector with respect to the local horizontal, deg
	AZ	Azimuth angle of the probe space-fixed velocity vector measured East of true North, deg
Row 29	XE, YE, ZE	Cartesian components of the Earth radius vector, km
	DXE, DYE, DZE	Cartesian components of the Earth space-fixed velocity vector, km/sec
Row 30	XT, YT, ZT	Cartesian components of the target radius vector, km
	DXT, DYT, DZT	Cartesian components of the target space-fixed velocity vector, km/sec
Row 31	LTE	Celestial latitude of the Earth, deg
	LOE	Celestial longitude of the Earth, deg
	LTT	Celestial latitude of the target, deg
	LOT	Celestial longitude of the target, deg
	RST	Sun–target range, km
	VST	Sun–target velocity, km/sec
Row 32	EPS	Earth–probe–Sun angle, deg
	ESP	Earth–Sun–probe angle, deg
	SEP	Sun–Earth–probe angle, deg
	EPM	Earth–probe–Moon angle, deg
	EMP	Earth–Moon–probe angle, deg
	MEP	Moon–Earth–probe angle, deg
Row 33	MPS	Moon–probe–Sun angle, deg
	MSP	Moon–Sun–probe angle, deg
	SMP	Sun–Moon–probe angle, deg
	SEM	Sun–Earth–Moon angle, deg
	EMS	Earth–Moon–Sun angle, deg
	ESM	Earth–Sun–Moon angle, deg
Row 34	EPT	Earth–probe–target angle, deg
	ETP	Earth–target–probe angle, deg
	TEP	Target–Earth–probe angle, deg
	TPS	Target–probe–Sun angle, deg
	TSP	Target–Sun–probe angle, deg
	STP	Sun–target–probe angle, deg

**See Appendix A.

Table D-2. *Ranger VII* trajectory key definitions (Cont'd)

Row 35	SET	Sun–Earth–target angle, deg
	STE	Sun–target–Earth angle, deg
	EST	Earth–Sun–target angle, deg
	RPM	Moon–probe radius distance, km
	RPT	Target–probe radius distance, km
	SPN	Sun–probe–near limb of Earth angle, deg
Row 36	GCE	Clock angle of Earth, deg
	GCT	Clock angle of target, deg
	SIP	Sun–probe–near limb of target angle, deg
	CPT	Canopus–probe–near limb of target angle, deg
	SIN	Canopus–probe–near limb of target angle, deg
	D1	Radius of a circle (target) used in construction of visible planet, cm
Row 37	REP	Earth–probe distance, km
	VEP	Velocity of the probe with respect to Earth, km/sec
	CPE	Canopus–probe–Earth angle, deg
	CPS	Canopus–probe–Sun angle, deg
	D2	Semiminor axis of ellipse used in construction of visible planet, cm
	D3	Distance from intersection of ellipse with circle to the diameter (of the circle) that is perpendicular to D1, in construction of visible planet, cm
Group G Row 38, 39		Inertial position of probe in a selenocentric equatorial system. The principal direction X is the vernal equinox direction of date and the principal plane XY is the geocentric equatorial plane of date. Z is along the direction of the Earth's spin axis of date.
Row 40, 41, 42		Selenocentric-fixed spherical coordinates of the probe, Sun, and Earth in a selenocentric equatorial system. The principal direction X is in the direction of the mean Moon–Earth line. The principal plane XY is the mean selenocentric equatorial plane. Z is along the direction of the Moon's mean spin axis. Miscellaneous parameters are also included.
Row 38	X, Y, Z	Cartesian components of the probe radius vector, km
	DX, DY, DZ	Cartesian components of the probe velocity vector, km/sec
Row 39	R	Probe radius distance, km
	DEC	Probe declination angle, deg
	RA	Probe right-ascension angle, deg
	V	Probe space-fixed velocity, km/sec
Row 39 (Cont'd)	PTH	Pitch angle of the probe space-fixed velocity vector with respect to the local horizontal, deg
	AZ	Azimuth angle of the probe space-fixed velocity vector measured East of true North, deg
Row 40	R	Probe radius distance, km
	LAT	Probe selenocentric latitude, deg
	LON	Probe selenocentric East longitude, deg
	VP	Probe selenocentric-fixed velocity, km/sec
	PTP	Pitch angle of the probe selenocentric-fixed velocity vector with respect to the local horizontal, deg
	AZP	Azimuth angle of the probe selenocentric fixed velocity vector measured East of the Moon's mean spin axis, deg
Row 41	LTS	Selenocentric latitude of the Sun, deg
	LNS	Selenocentric longitude of the Sun, deg
	LTE	Selenocentric latitude of the Earth, deg
	LNE	Selenocentric longitude of the Earth, deg
Row 42	ALT	Altitude of the probe above the Moon's surface, km
	SHA	Sun shadow parameter, km
	ALP	Illuminated crescent orientation viewing angle, deg
	DR	First time derivative of the probe radius distance, km/sec
	DP	First time derivative of the probe radius direction, deg/sec
	ASD	Angular semidiameter of Moon as seen from the probe, deg
Row 43	HGE	Right ascension of Earth in probe coordinate system,† deg
	SVL	Declination of the Moon in probe coordinate system,† deg
	HNG	Right ascension of the Moon in probe coordinate system,† deg
	SIA	Earth–probe–Moon angle minus ASD, deg
Group H		Characteristics of the selenocentric conic in the geocentric equatorial system described under Group B, except centered at the Moon.

†Same coordinate system as defined under Group B except centered at the probe.

Table D-2. *Ranger VII* trajectory key definitions (Cont'd)

Row 44	SMA	Semimajor axis, km
	ECC	Eccentricity
	B	The magnitude of the impact parameter,** km
	SLR	Semilatus rectum, km
	APO	Apogee distance, km
	RCA	Magnitude of the closest approach vector, km
Row 45	VH	Hyperbolic excess speed, km/sec
	C3	Twice the energy (*vis viva* energy integral, km^2/sec^2)
	C1	Angular momentum, km^2/sec
	TFP	Time from pericenter passage, sec
	TF	Time from injection to pericenter passage, hr
	LTF	Linearized time-of-flight, hr
Row 46	TA	True anomaly, deg
	MTA	Maximum true anomaly, deg
	EA	Eccentric anomaly, deg
	MA	Mean anomaly, deg
	C3J	Earth–Moon Jacobi constant, km^2/sec^2
	TFI	Time from injection, hr
Row 47	ZAE	Angle between the incoming asymptote and the Moon–Earth vector, deg
	ZAP	Angle between the incoming asymptote and the Moon–Sun vector, deg
	ZAC	Angle between the incoming asymptote and the Moon–Canopus vector, deg
	DEF	Angle between the incoming and outgoing asymptotes, deg
	IR	Maximum **B** vector magnitude for lunar impact, km
	GP	Angle between the incoming asymptote and its projection on the lunar orbital plane.
Row 48	OP1	Spacecraft nominal terminal maneuver first pitch turn, deg
	OY	Spacecraft nominal terminal maneuver yaw turn, deg
	OP2	Spacecraft nominal terminal maneuver second pitch turn, deg
Group I		Characteristics of the selenocentric conic in the specified "principal plane" coordinate system
Row 49	X, Y, Z	Cartesian components of the probe radius vector, km
	DX, DY, DZ	Cartesian components of the probe space-fixed velocity vector, km/sec

Row 50	INC	Inclination of the orbit plane to the equatorial plane, deg
	LAN	Longitude of the ascending node, deg
	APF	Argument of pericenter, deg
	MX, MY, MZ	Components of a unit vector which lies in the orbit plane and is normal to the radius vector **R** $\mathbf{M} = \mathbf{W} \times \frac{\mathbf{R}}{\lvert\mathbf{R}\rvert}$
Row 51	WX, WY, WZ	Components of a unit vector normal to the conic $\mathbf{W} = \frac{\mathbf{R} \times \mathbf{V}}{\lvert\mathbf{R} \times \mathbf{V}\rvert}$
	PX, PY, PZ	Components of a unit vector in the direction of perigee
Row 52	QX, QY, QZ	Components of a unit vector perpendicular to the perigee direction, vector **P**, and being in the orbit plane $\mathbf{Q} = \mathbf{W} \times \mathbf{P}$
	RX, RY, RZ	Components of the unit vector **R****
Row 53	BX, BY, BZ	Components of the impact parameter **B**,** km
	TX, TY, TZ	Components of the unit vector **T****
Row 54	SXI, SYI, SZI	Components of the unit vector $\mathbf{S}_I$** along the direction of the incoming asymptote
	DAI	Declination of the outgoing asymptote,** deg
	RAI	Right ascension of the incoming asymptote,** deg
Row 55	SXO, SYO, SZO	Components of the unit vector $\mathbf{S}_O$** along the direction of the outgoing asymptote
	DAO	Declination of the outgoing asymptote,** deg
	RAO	Right ascension of the outgoing asymptote,** deg
Row 56	ETE	Angle between the **T** vector and the projection of the Moon–Earth vector on the **R**–**T** plane, deg
	ETS	Angle between the **T** vector and the projection of the Moon–Sun vector on the **R**–**T** plane, deg
	ETC	Angle between the **T** vector and the projection of the Moon–Canopus vector on the **R**–**T** plane, deg

**See Appendix A.

Table D-2. *Ranger VII* trajectory key definitions (Cont'd)

Row 57	BT††	Projection of the impact parameter **B**** upon the vector **T**, km
	BR††	Projection of the impact parameter **B**** upon the vector **R**, km
	B	The magnitude of the impact parameter,** km
	THA	Angle between the parameter **B** and the vector **T**, measured clockwise from **T**, deg
Group J		Cartesian coordinates and epoch of injection conditions in the geocentric equatorial system described under Group B.
Row 58	XOCTAL, YOCTAL, ZOCTAL	Cartsian components of the probe radius vector at injection in octal representation, km
	ẊOCTAL, ẎOCTAL, ŻOCTAL	Cartesian components of the probe space-fixed velocity vector at injection in octal representation, km/sec

Row 59	Epoch of injection
YY	Years past 1900
MM	Month
DDD	Day of month
HH	Hours
TT	Minutes
SSSSS	Milliseconds
SOCTAL	Seconds in octal representation, GMT
	Time past midnight on day (DD), month (MM), and year (YY + 1900) at which the injection epoch occurs is the time determined by the sum of HH, TT, SSSSS and SOCTAL.

††Principal planes:
- Q Earth equatorial plane
- C Ecliptic plane
- O Lunar orbital plane
- T True lunar equator.

**See Appendix A.

Table D-3. *Ranger VII* trajectory constants and conversion factors

Constants	Conversion factors
GM_{Sun}	$1.32715445 \times 10^{11}$ km³/sec²
GM_{Venus}	3.247695×10^{5} km³/sec²
$GM_{\oplus}$*	3.986032×10^{5} km³/sec²
$GM_{\oplus-\mathfrak{C}}$	4.03503×10^{5} km³/sec²
$GM_{\mathfrak{C}}$**	4.900759×10^{3} km³/sec²
GM_{Mars}	4.297780×10^{4} km³/sec²
$GM_{Jupiter}$	1.267106×10^{8} km³/sec²
M_{Sun}/M_{Venus}	408645
M_{Sun}/M_{Earth}	332951.3
M_{Earth}/M_{Moon}	81.335
$M_{Sun}/M_{Earth-Moon}$	328908
M_{Sun}/M_{Mars}	3,088,000
$M_{Sun}/M_{Jupiter}$	1047.39
Equatorial radius of Earth	6378.3149 km
1 AU	1.495990×10^{8} km
Ellipticity of Earth	1/298.3
Conversion from feet to meters	0.3048
Atmospheric model	1959 ARDC
Sidereal rotation rate of Earth	4.1780742×10^{-3} deg/sec
Universal constant of gravitation	6.671×10^{-20} km³/kg sec²
Speed of light	2.997925×10^{5} km/sec
Mean Moon radius	1738.09 km

Constants	Conversion factors
Moon moments of inertia about principal axis	$A = 0.88746 \times 10^{29}$ kg km² $B = 0.88764 \times 10^{29}$ kg km² $C = 0.88801 \times 10^{29}$ kg km²
Lunar and solar ephemerides	The Moon and Sun positions are obtained from the joint JPL–STL ephemerides. For purposes of converting into kilometers, the conversion factors are: 1 AU = 1.495990×10^{8} km 1 e.r. = 6378.3149
Geometrical Earth model, used in locating tracking and launching facilities upon the Earth	Clarke spheroid of 1866 a = 6378.2064 km b = 6356.5838 km $e^2 = 0.006768657997291$

Earth potential function:

$$\Phi(R, \phi) = \frac{GM_{\oplus}}{R}\left[1 + \frac{JR_E^2}{3R^2}(1 - 3\sin^2\phi) + \frac{H}{5}\frac{R_E^3}{R^3}(3 - 5\sin^2\phi)(\sin\phi) + \frac{D}{35}\frac{R_E^4}{R^4}(3 - 30\sin^2\phi + 35\sin^4\phi)\right]$$

where
- R = geocentric distance
- ϕ = geocentric latitude
- $J = 1.62345 \times 10^{-3}$
- $H = -0.575 \times 10^{-5}$
- $D = 0.7875 \times 10^{-5}$

*3.9860005 × 10⁵ km³/sec² was used for the premidcourse orbit.
**4.9007604 × 10³ km³/sec² was used for the premidcourse orbit.

APPENDIX G

ODP format description

Block No. references are to Appendixes E and F. All units are in kilometers and seconds unless otherwise specified.

Block No. 1 — Control card input.

Block No. 2 — Input covariance matrix of estimated parameters from postmaneuver data a priority.

Block No. 3 — Inverse of Block No. 2

Block No. 4 — Trajectory based on injection conditions from previous iteration. Its format is explained in Appendix D.

Block No. 5 — The normal equation coefficients combined with the a priori matrix at injection epoch.

Block No. 6 — Correlation matrix based on Block No. 5

Block No. 7 — Solution vector and statistics of estimated parameters from last iteration (see next page for explanation of format).

Block No. 8 — Covariance matrix of estimated parameters, at injection epoch, from last iteration.

Block No. 9 — Correlation matrix of estimated parameters, at injection epoch, from last iteration.

Block No. 10 — Residual listings and data statistics for the tracking stations. First the residuals will be listed and then followed by the statistics.

BLOCK 8

The above sequence is repeated until the orbit converges. In the last iteration a trajectory based on the converged estimated parameters is run out to lunar encounter. See Appendix D for explanation of trajectory format.

Following the trajectory printout is the U matrix which maps the covariance matrix at injection to encounter. Immediately below the U matrix is the covariance matrix on the estimated parameters at impact or closest approach epoch. This is formed by mapping the covariance matrix at injection to impact in double precision.

There are three blocks following the covariance matrix. The first block is a covariance matrix N formed by mapping the upper 6×6 matrix of the covariance of impact into a new coordinate system (explained in Appendix A of this Report) (σ^2_{TL} is in hr^2). The second block is simply the correlation matrix of the first block covariance matrix. The third block is a mapping matrix which maps injection components into the **B·T**, **B·R**, etc. system.

B = The vector measured from the center of the Moon perpendicular to the incoming asymptote (in kilometers).

B·RO = The **B** vector dotted on the **R** axis in km (**T** axis in the Moon's orbital plane).

B·TO = The **B** vector dotted on the **T** axis in km (**T** axis in the Moon's orbital plane).

B·RT = The **B** vector dotted on the **R** axis in km (**T** axis in the equatorial plane of the Moon).

RESIDUAL LISTING FORMAT

Frequency XXXX.X Last digits in transmitter, frequency 2966 XXXX.X in cps

GMT	*TC*	Q		*CC3*	
XX XX XX hr min sec	X Doppler count time in sec	X Transmitting station	.XXXXXXXX XX Two-way doppler (CC3) value in cps (floating point number)	.XXX XX Associated weight in floating point	.XXXX[16] Residual (observed minus calculated) in cps

[16]Residuals followed by an asterisk (*) have been deleted from fit.

B·TT = The **B** vector dotted on the **T** axis in km **T** axis in the equatorial plane of the Moon).

TL = Linearized time of flight in hours.

SMAA = The largest eigenvalue of the upper 2×2 of the N matrix (commonly called the semimajor axis of a 40% dispersion ellipse in the **B** plane).

SMIA = The semiminor axis of the dispersion ellipse or the other eigenvalue of the upper 2×2.

THETA = The orientation angle of the semimajor axis of the dispersion ellipse measured counterclockwise from the **T** axis.

DEL T = Uncertainty in the time of flight in sec.

DEL B = $(N_{11} + N_{22})^{1/2}$ where N's are from the first block of this sheet.

DEL S = V_∞ (*DEL T*) The position uncertainty in the direction of the incoming asymptote. Where V_∞ = hyperbolic excess velocity in km/sec.

TF = Orbital time of flight, in hours from injection epoch to impact or closest approach.

The block following the **B** plane parameters is formed by rotating the upper 3×3 of the covariance matrix N (target orbital plane) into the target equatorial plane.

BLOCK 7

JOB TITLE

Iteration number	Epoch year/month/day			XX XXX XX	Clock XXXXXX	SOS* XXXXX QSOS** XXXXX
	GMT			hr, min, sec	(PC time now) hr, min, sec	Floating pointing numbers
Q	DQ	STDEVDQ	OLD Q	NEW Q	NOMINAL Q	DQ (NOM)
X, Y, Z = Position space-fixed Cartesian component in km DX, DY, DZ = Velocity space-fixed Cartesian in km/sec RI = Radius in km $KE = GM_e$ in km^3/sec^2 LA = Latitude deg RE in = Radius of Earth to scale ephemeris in km LO = Longitude in deg $KM = GM_\zeta$ in km^3/sec^2	Difference in estimated parameters from previous iteration and this iteration	Standard deviations on estimated parameters	Value of estimated parameters from previous iteration (Initial estimate on 1st iteration)	Value of estimated parameters on this iteration	Initial estimate of parameters	Total difference in new Q and nominal Q

*Weighted sum of the squares of the residuals.

**Weighted sum of the squares of the residuals plus the product $\delta x^T \Gamma^{-1} \delta x$ where δx is the difference in the a priori Q and the value of Q on the particular iteration, and Γ is on a priori covariance on Q.

ACKNOWLEDGEMENT

The authors gratefully acknowledge the support of personnel in JPL Sections 312, 317, 318 and 332, especially the trajectory program developer D. B. Holdridge; the orbit determination program developers J. D. Anderson, M. R. Warner and M. W. Nead; the tracking data editing program developer R. E. Holzman; and the maneuver programmer R. W. Carpenter.

The advance unedited proofs of the new lunar charts were made available through the courtesy of the United States Air Force Aeronautical Chart and Information Center, St. Louis, Missouri.

Additional contributors who helped to analyze, program, and expedite this Report were D. L. Cain, T. W. Hamilton, W. E. Kirhofer, V. C. Clarke, J. D. Anderson, C. B. Solloway, T. Moyer, D. E. Willingham, J. P. Fearey, W. D. Chaney, C. Cary, G. L. Bolta, L. Dicken, J. M. Carnakis, J. Borthwick and P. M. Muller. The authors regret that the above list is incomplete and extend their appreciation to all other contributors.
